

WETRAX⁺

Future changes in weather patterns and implications for low flow

Selina Thanheiser, Markus Homann, Christoph Beck, Andreas Philipp, Jucundus Jacobeit

Institute of Geography, University of Augsburg, Germany

Agenda

1. Background

2. Data and Methods for determining weather patterns/circulation types

3. Drought relevant Circulation Types for the winter and the summer half year

4. Implications for Low Flow in the Isar river

5. Future Changes in frequencies, persistence and within-type characteristics of circulation types

6. Summary and Conclusions

1 Background

WETRAX⁺ Project - Weather Patterns, Cyclone Tracks and related precipitation Extremes

Effects of climate change on extreme areal precipitation and drought periods in southern central Europe

Main contributions of University of Augsburg:

- determination of circulation types that are important for extremes
- estimation of future changes in frequencies and characteristics of relevant types

 Bundesministerium
Nachhaltigkeit und Tourismus

2 Data for determining weather patterns/circulation types

Observational-, reanalysis- and climate model data

Data	Variable	Time period	Resolution	Name
Observational data	Gridded Precipitation data [mm] „Target variable“	1961-2015	24 hours / 6x6km	Central Institute for Meteorology & Geodynamics Austria
Reanalysis data	Mean sea level pressure [hPa], Relative humidity [%]*, U-component of wind [m/s]*, V-component of wind [m/s]*, Vertical velocity [hPa/h]* Geopotential [gpm]** Temperature [K]*** Determination of circulation types	1958-2017	6 hours / 1.25°	JRA55 – Japanese 55-year Reanalysis (Japan Meteorological Agency)
Regional climate model data	Mean sea level pressure [hPa], Temperature [K]*** Precipitation [mm] Projection of circulation types	1971-2100	24 hours / 0.11°	EURO-CORDEX (Coordinated Downscaling Experiment – European Domain)

* 700 hPa Niveau ** 500 hPa Niveau *** 2 m

2 Methods for determining weather patterns/circulation types

Regionalisation of gridded precipitation data

In a first step, regions with similar precipitation variability between 1961-2017 on a yearly scale were determined by using an s-mode principal component analysis.

The result are six regions of similar precipitation variability. The precipitation data enters the classification as a target variable in the form of **six time series, one for each region of similar precipitation variability.**

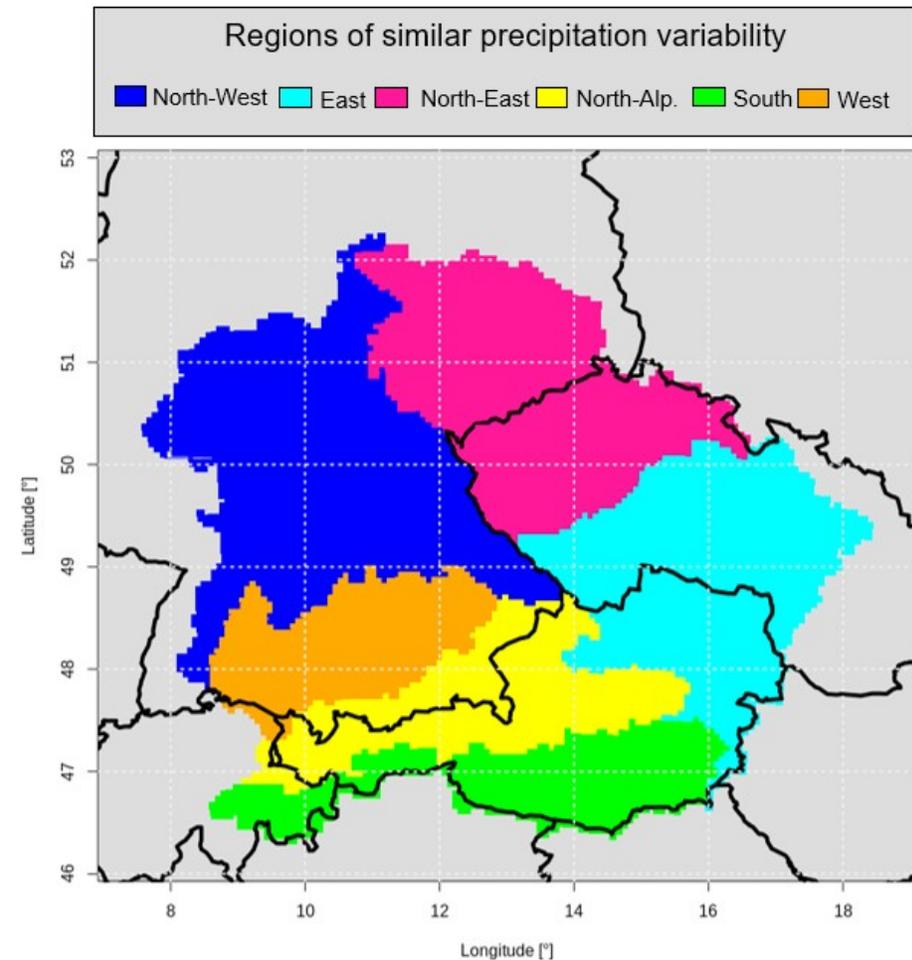

Figure 1: Regions of similar precipitation variability in the study area resulting from s-modal principal component analysis on a monthly basis with gridded WETRAX+ precipitation dataset (1961-2017).

2 Methods for determining weather patterns/circulation types

Weather/circulation typing

Software

Cost733class is a FORTRAN software package for developing and evaluating weather and circulation type classifications.

(Philipp et al. 2010)

Classification

Non-hierarchical cluster analysis: SANDRA (simulated annealing and diversified randomization) for an optimal division of classes.

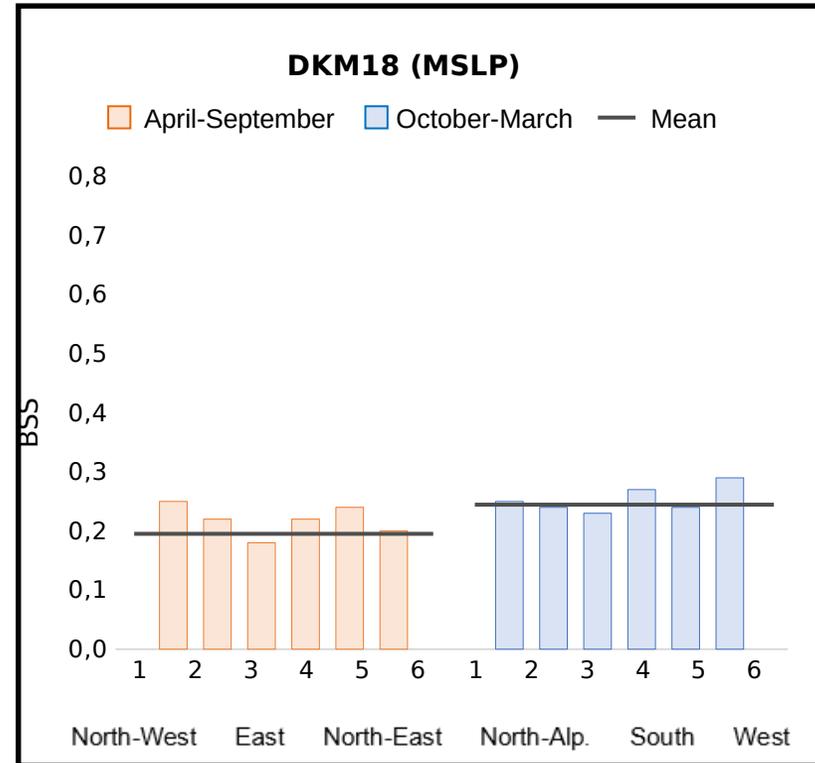

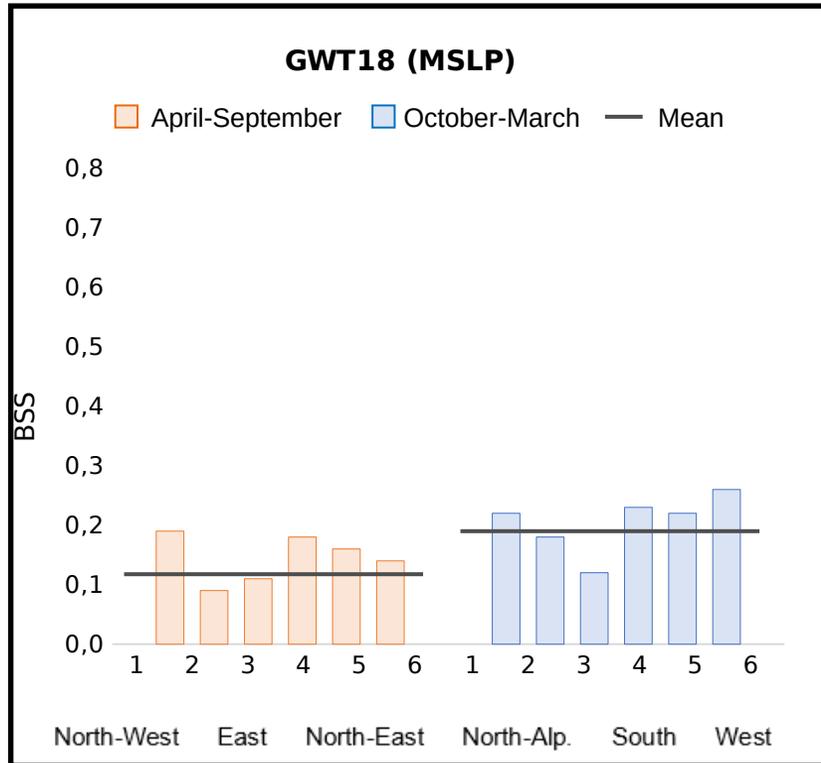

Evaluation

The Brier-Skill-Score (BSS) is based on the Brier Score (BS), a statistical index which can be used to validate probability forecasts.

Aim → optimizing the synoptic skill of the classification
(discriminatory power for target variable precipitation)

2 Methods for determining weather patterns/circulation types

Optimized circulation type classification: **GWT vs. DKM – MLSP only**

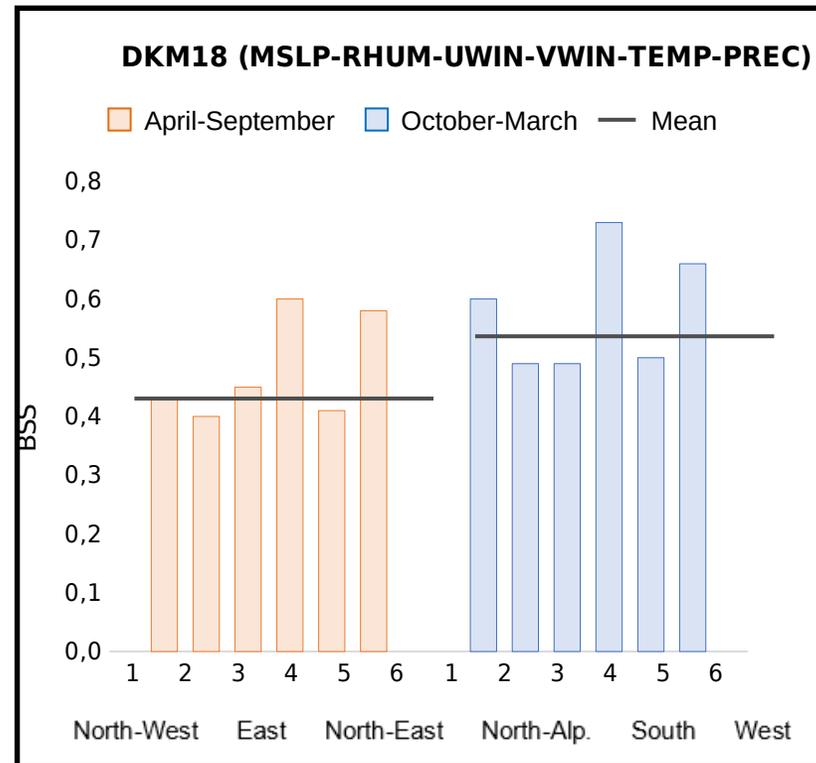

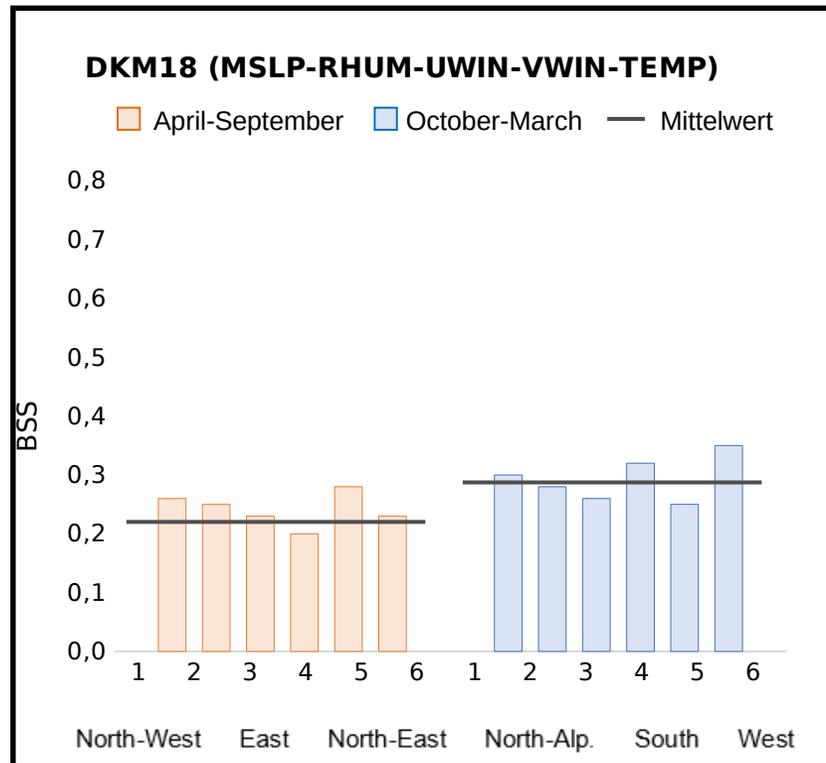

Increasing synoptic skill
from
semi-objective
to
objective
classifications

Region-specific Brier skill score (BSS) for April-September and October-March using GWT and DKM classification with 18 classes for mean sea level pressure in hPa (MSLP). The black horizontal line is mean BSS of all regions.

2 Methods for determining weather patterns/circulation types

Optimized circulation type classification: **DKM18 all Variables vs. all Variables with PREC**

Increasing synoptic skill
by means of
multi-parameter
and
„conditional“
classifications

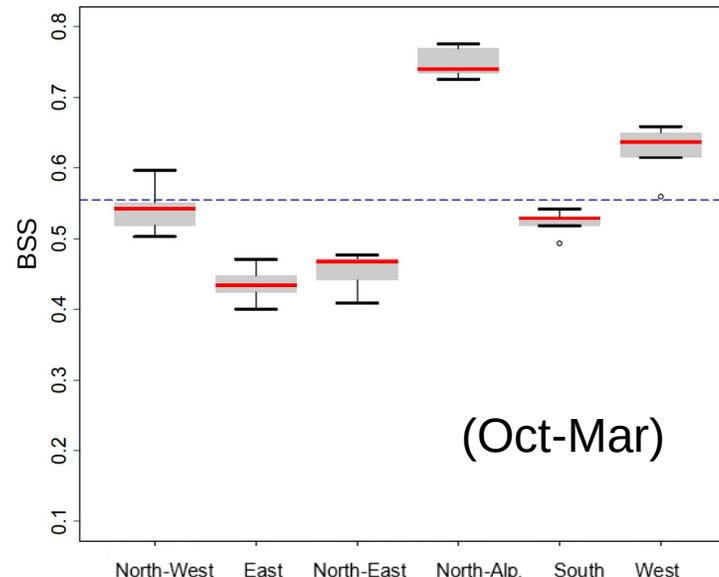

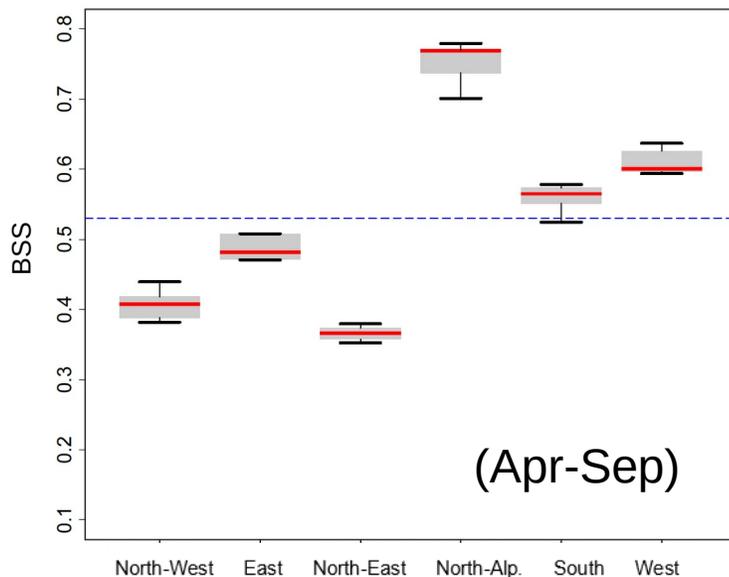

Region-specific Brier skill score (BSS) for April-September and October-March using DKM classification with 18 classes and the weighted parameters MSLP (1), RHUM700 (2), U-Wind700 (1), V-Wind700 (1), TEMP (3), and DKM classification conditioned on the target variable PREC (18). The black horizontal line is the mean BSS of all regions.

2 Methods for determining weather patterns/circulation types

Optimized circulation type classification

Final variables and weights – Classification (SAN18) **drought** (Apr-Sep, Oct-Mar)

Variable	Mean sea level pressure	Relative humidity	U-component of wind	V-component of wind	Temperature	Precipitation
Unit	hPa	%	m/s	m/s	K	mm
Level		700 hPa	700 hPa	700 hPa	2 m	
Weight	1	2	1	1	3	18

Brier skill scores (BSS) of classifications with respect to dryness. MSLP(1), RHUM700(2), UCW700(1), VCW700(1), TEMP(3), PREC(18). Mapping performance of circulation type classification with respect to precipitation in terms of Brier Skill Score (BSS) according to Schiemann & Frei (2010) (y-axis) in the six regions of similar precipitation variability (x-axis), boxplots: BSS range across validation periods.

3 Drought relevant circulation types

Percentage of circulation type (CT) days April-September and October-March associated with **drought** in regions of similar precipitation variability

April-September

Definition of drought-relevant circulation types: All circulation types that are associated with a precipitation mean below the 20th percentile (1961-2017) on at least 20% of all CT days in at least one region.

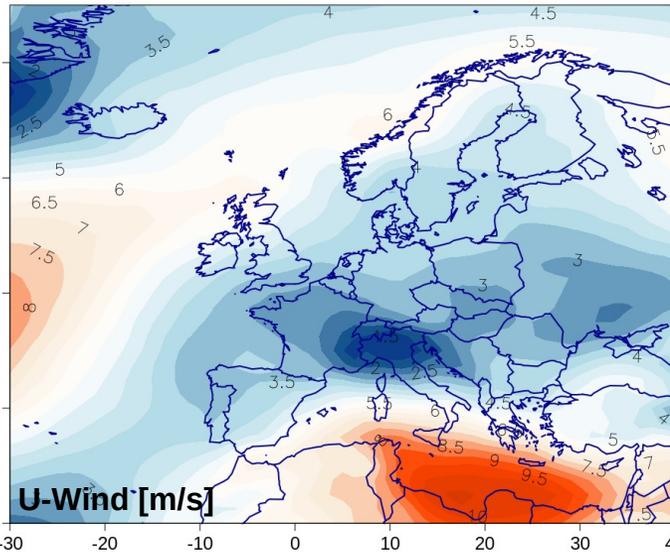

Drought relevant circulation type 12 April-September

Type 12 – Mean Sea Level Pressure

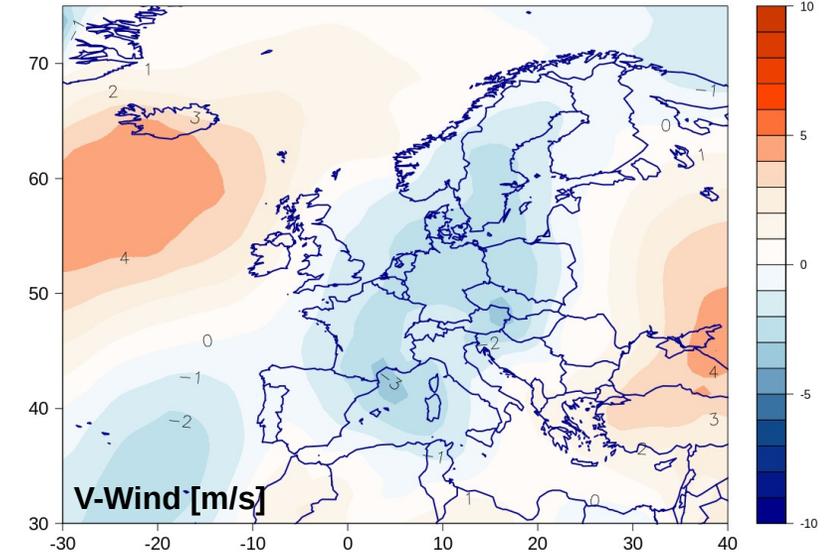

Zentroid

Type 12 – U-Component of Wind

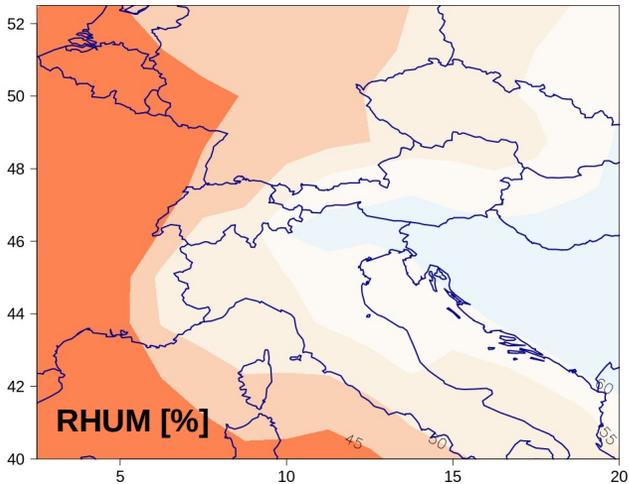

Zentroid

Type 12 – V-Component of Wind

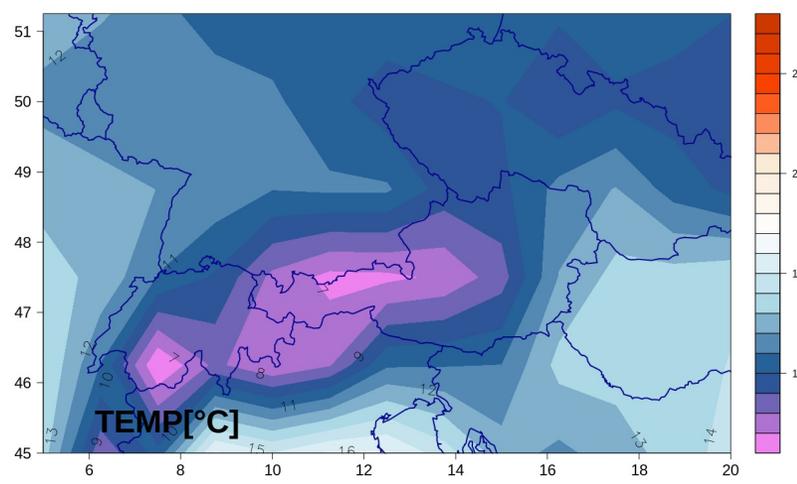

entroid

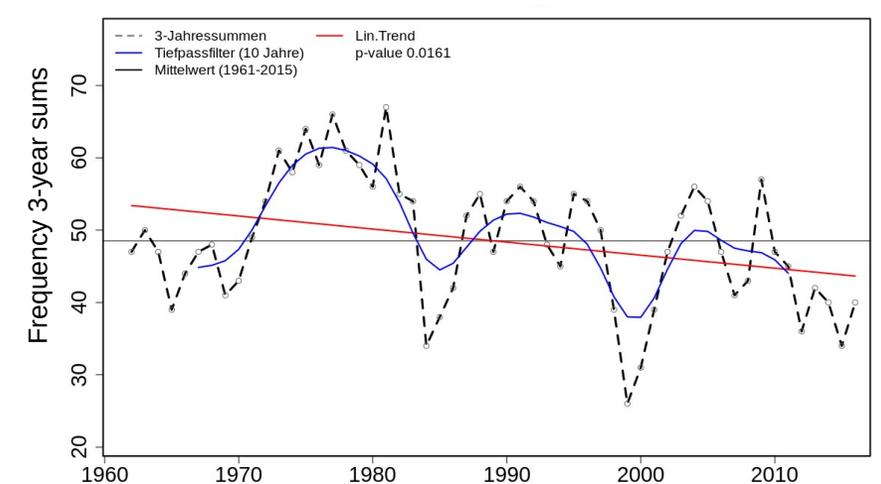

Type 12 – Relative Humidity

Type 12 – Temperature

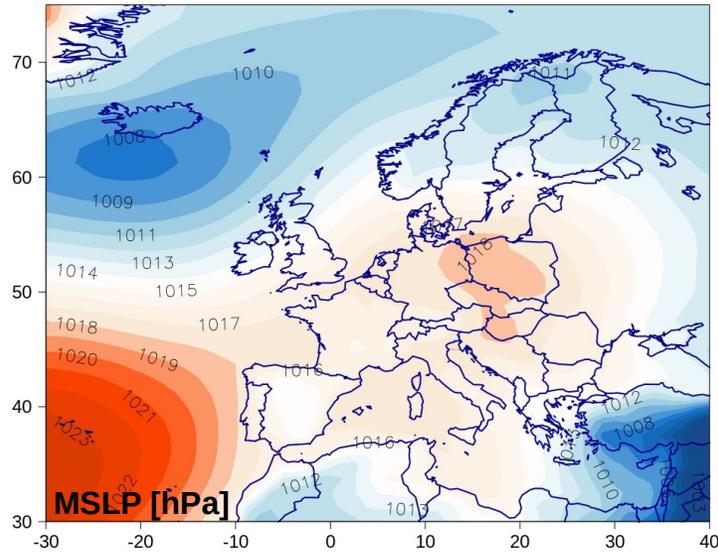

Type 12 – Frequency

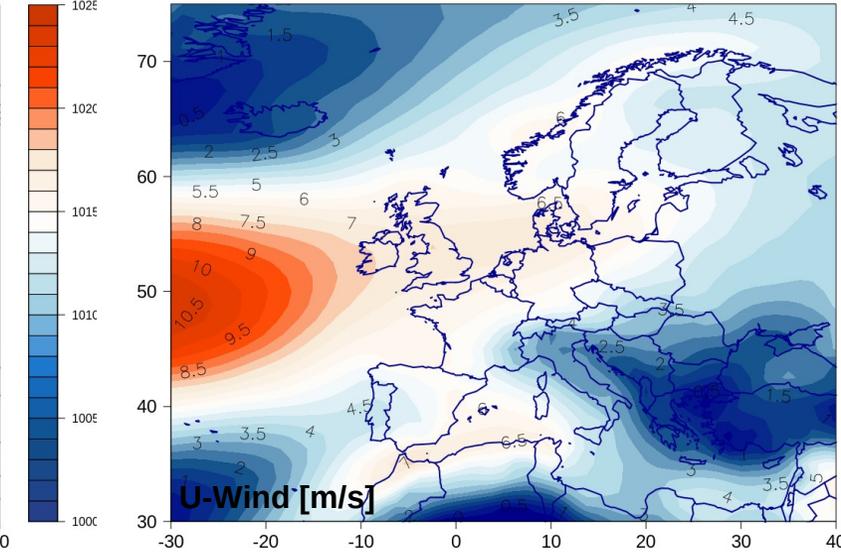

Drought relevant CT 12 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

Drought relevant circulation type 14 April-September

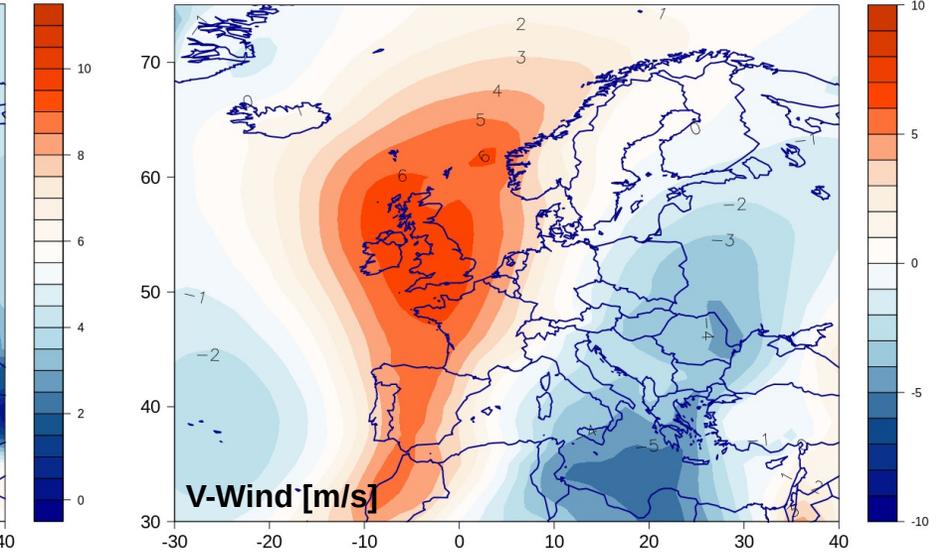

Type 14 – Mean Sea Level Pressure

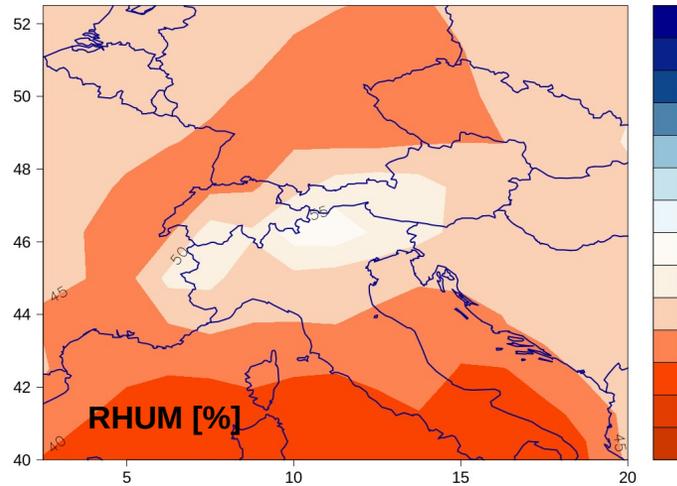

Type 14 – U-Component of Wind

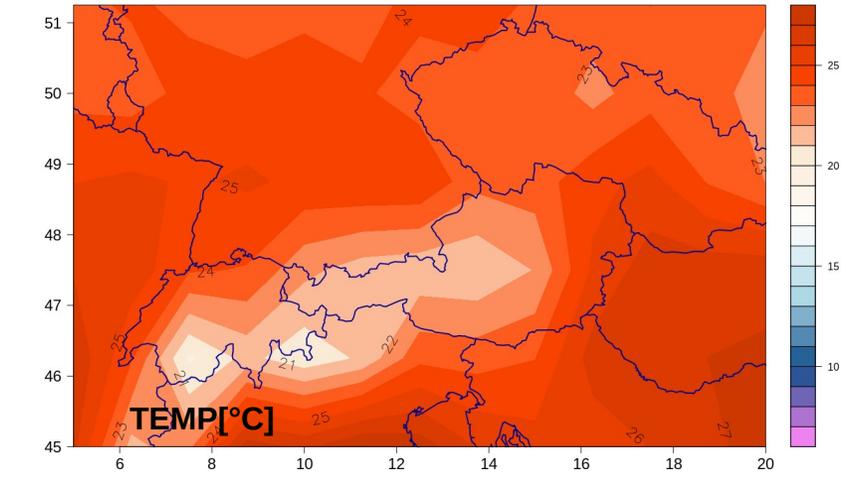

Type 14 – V-Component of Wind

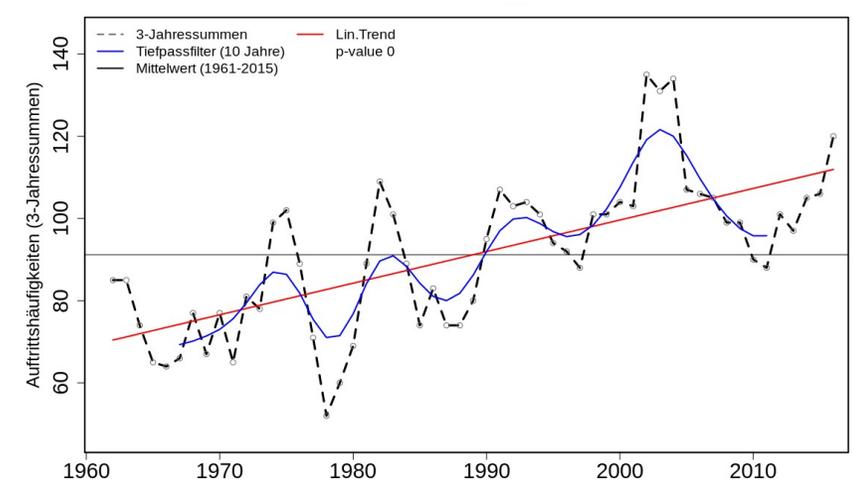

Type 14 – Relative Humidity

Type 14 – Temperature

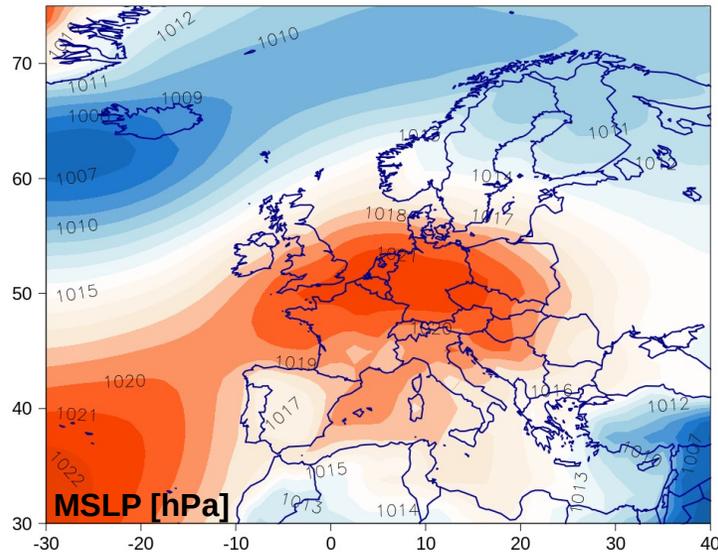

Type 14 – Frequency

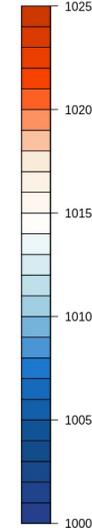

Drought relevant CT 16 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

Drought relevant circulation type 16 April-September

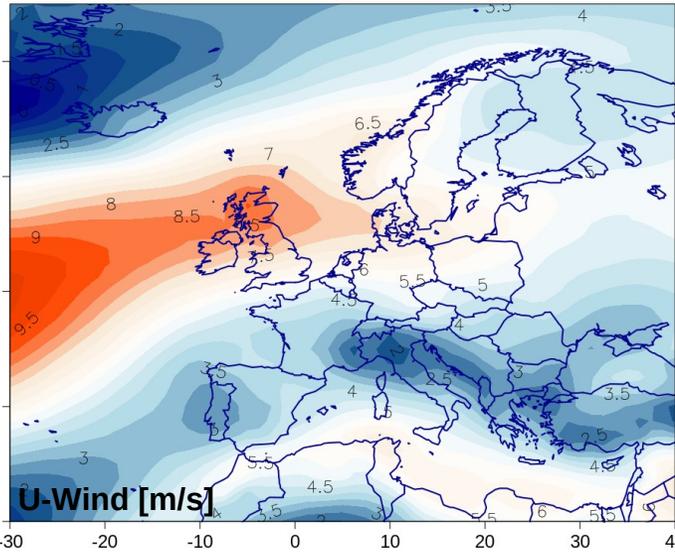

Type 16 – Mean Sea Level Pressure

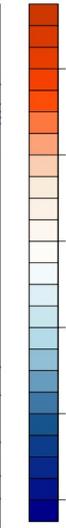

Zentroid

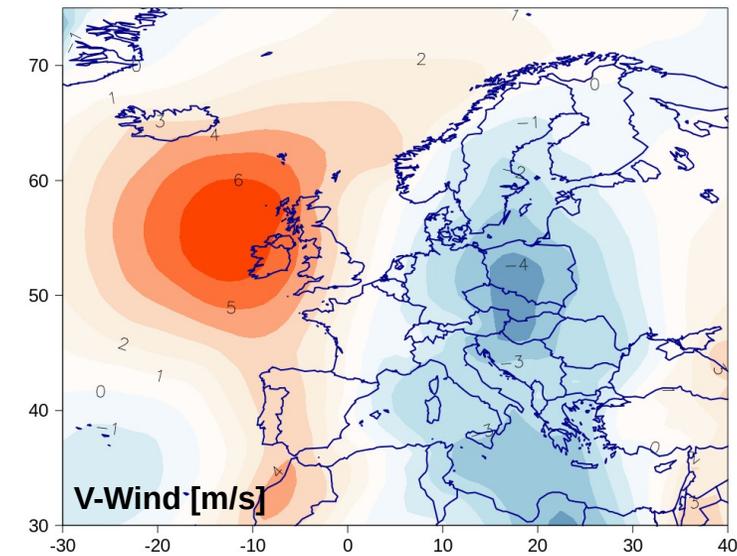

Type 16 – U-Component of Wind

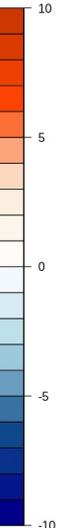

Zentroid

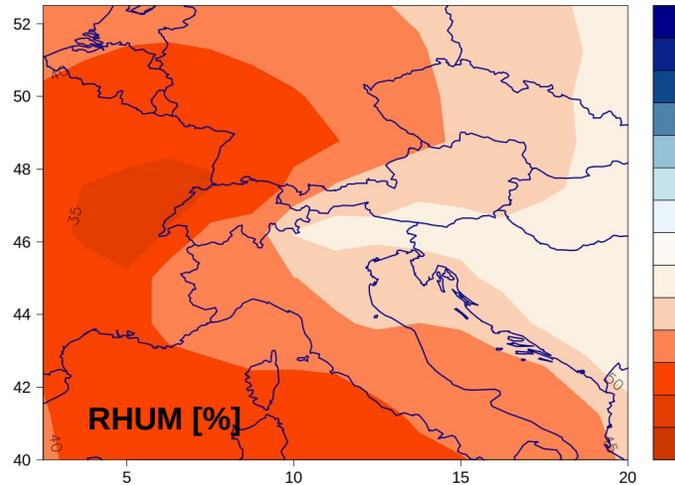

Type 16 – V-Component of Wind

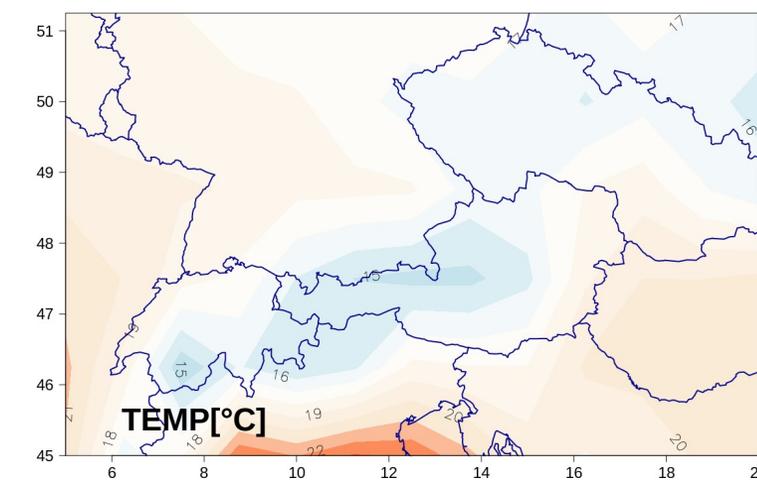

entroid

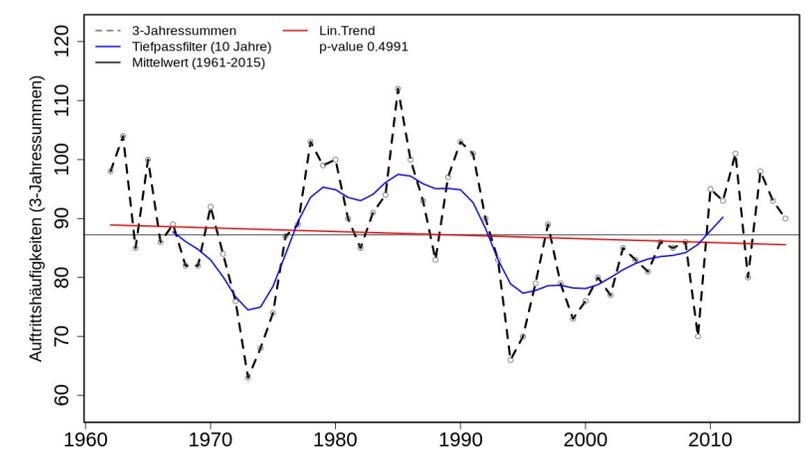

Type 16 – Relative Humidity

Type 16 – Temperature

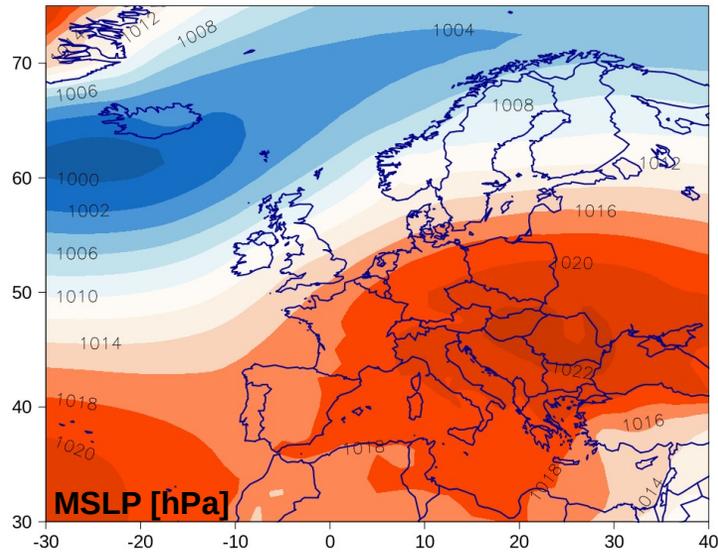

Type 16 – Frequency

Drought relevant CT 16 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

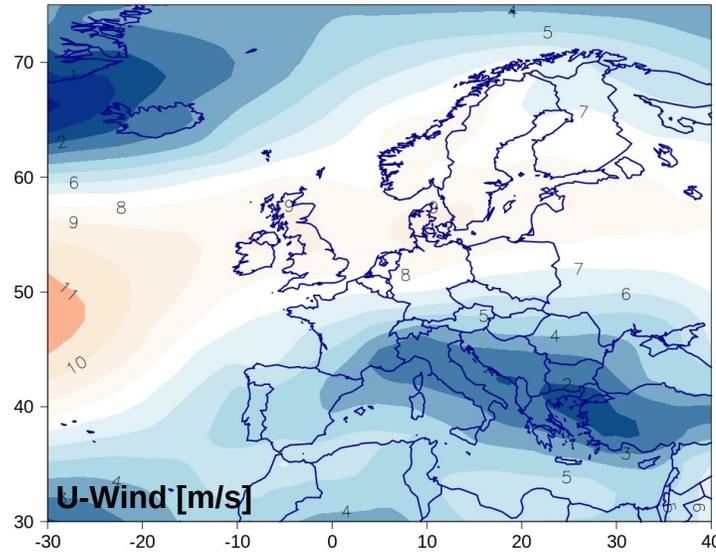

Drought relevant circulation type 10 October-March

Type 10 – Mean Sea Level Pressure

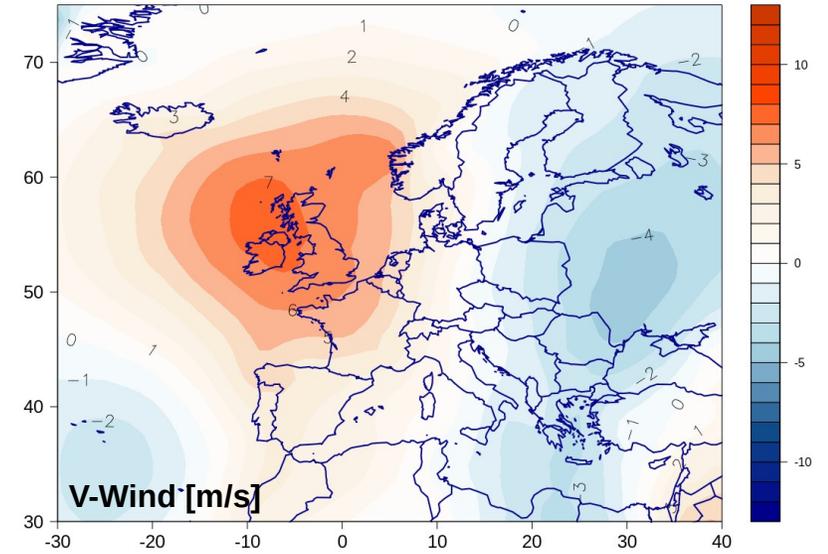

Zentroid

Type 10 – U-Component of Wind

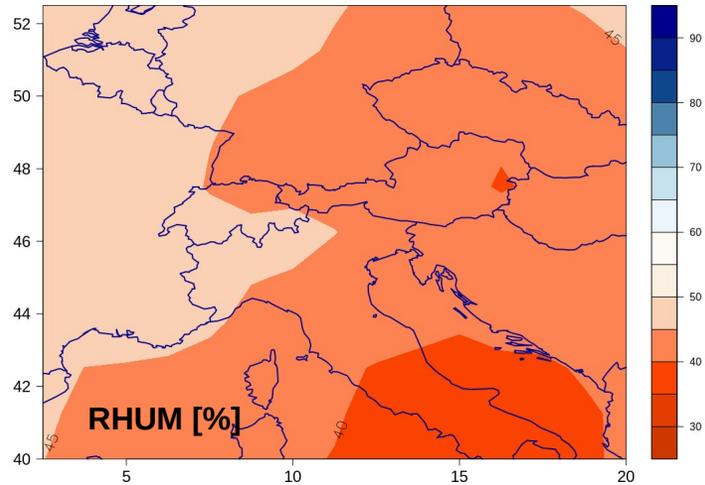

Zentroid

Type 10 – V-Component of Wind

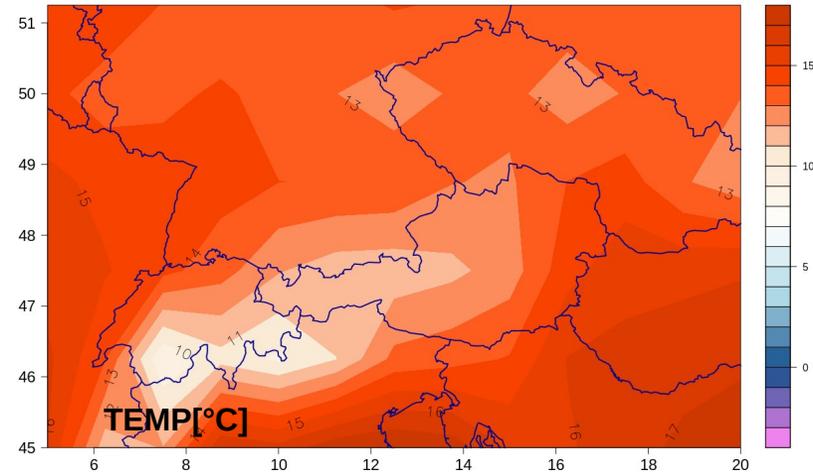

Zentroid

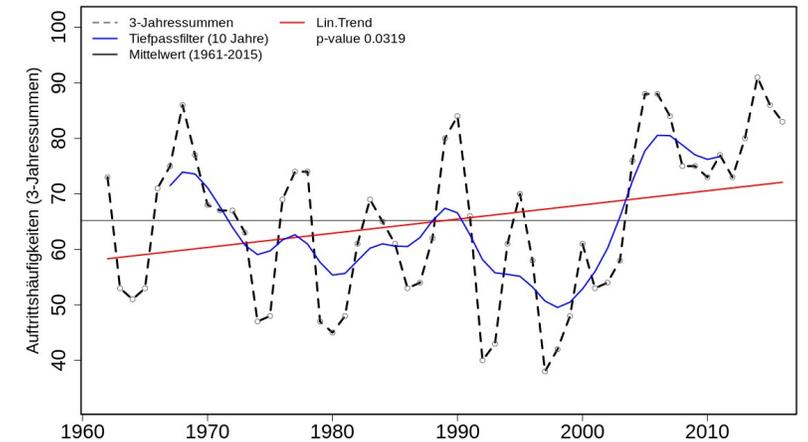

Type 10 – Relative Humidity

Type 10 – Temperature

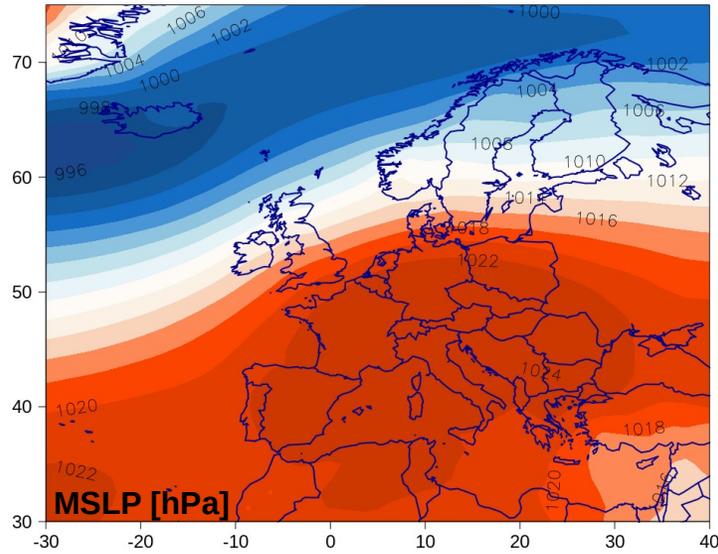

Type 10 – Frequency

Drought relevant CT 10 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

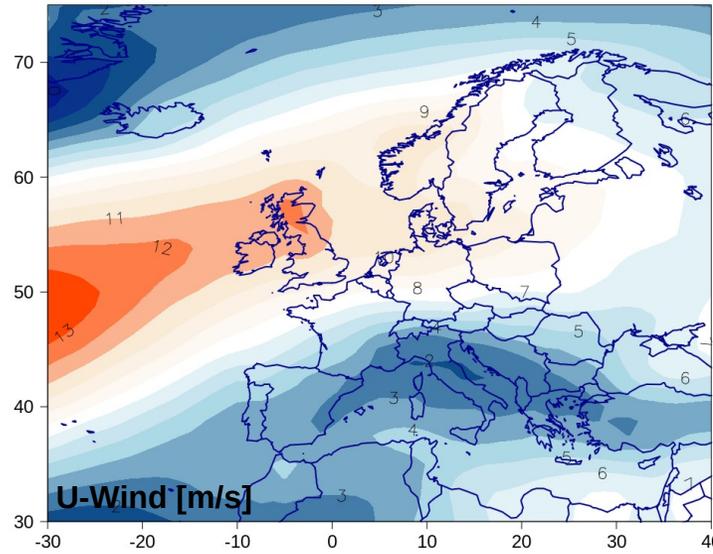

Drought relevant circulation type 14 October-March

Type 14 – Mean Sea Level Pressure

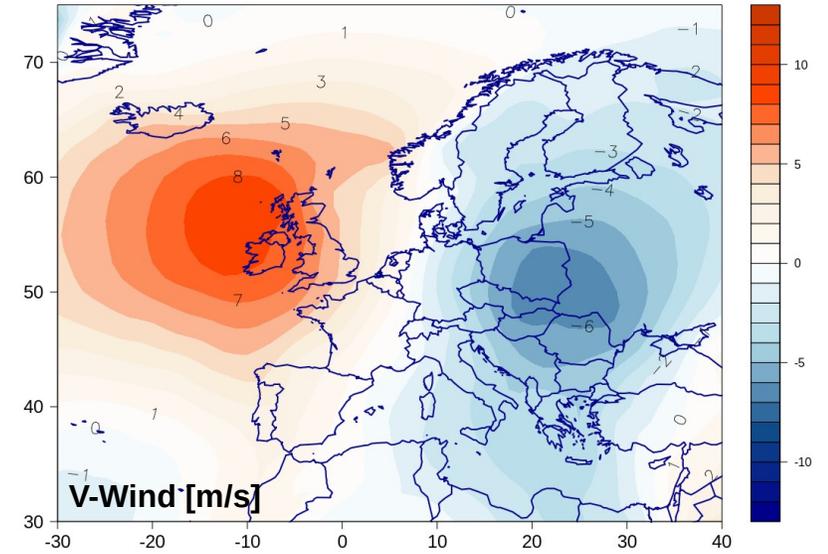

Zentroid

Type 14 – U-Component of Wind

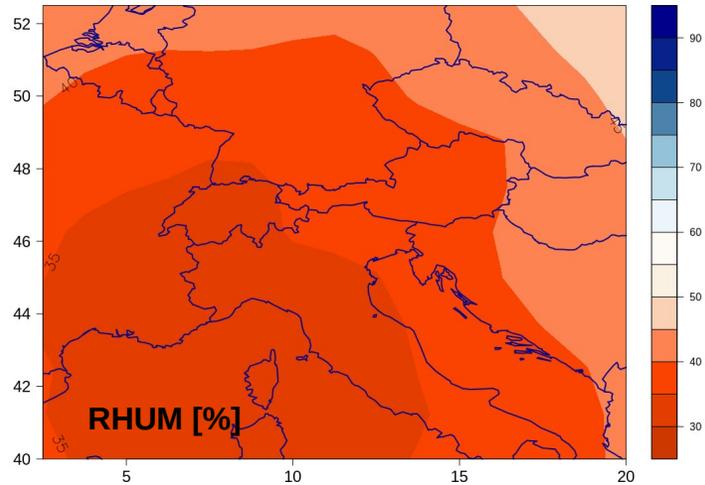

Zentroid

Type 14 – V-Component of Wind

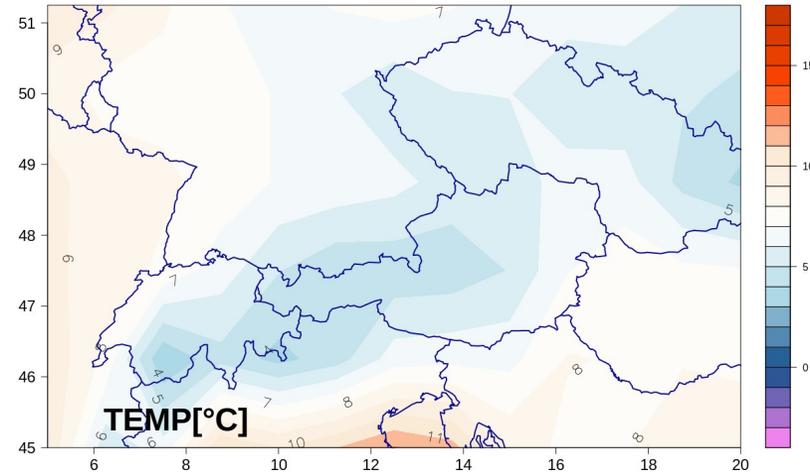

Zentroid

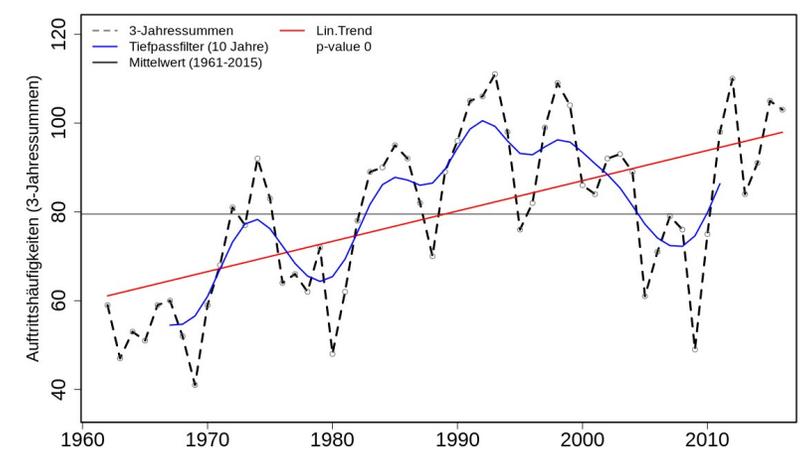

Type 14 – Relative Humidity

Type 14 – Temperature

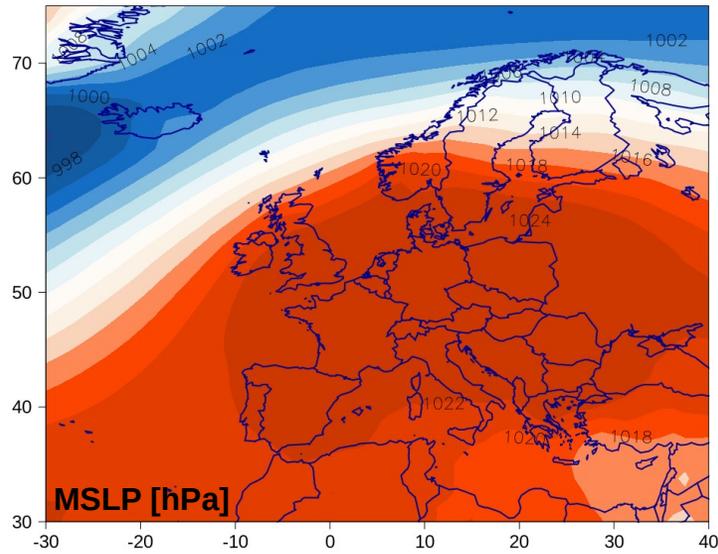

Type 14 – Frequency

Drought relevant CT 14 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

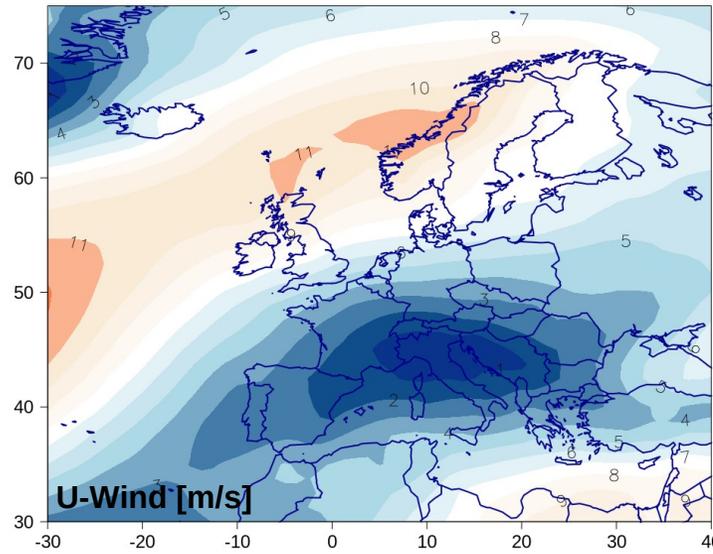

Drought relevant circulation type 17 October-March

Type 17 – Mean Sea Level Pressure

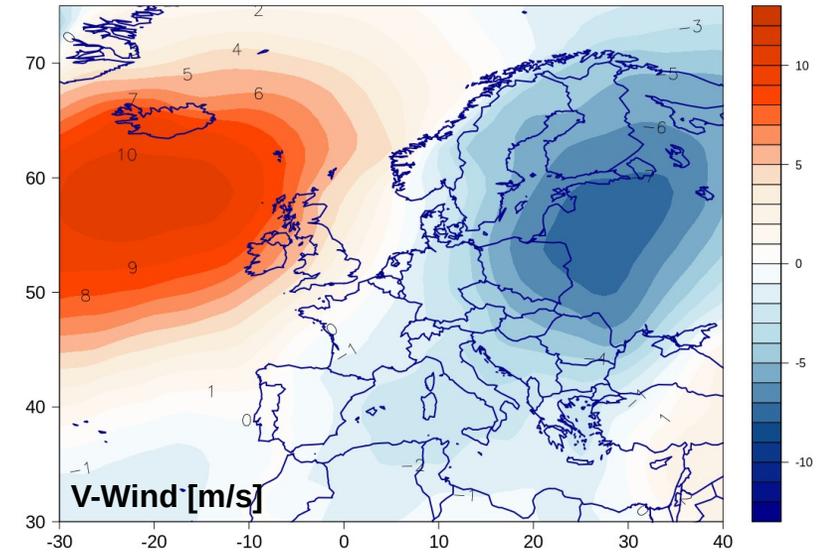

Zentroid

Type 17 – U-Component of Wind

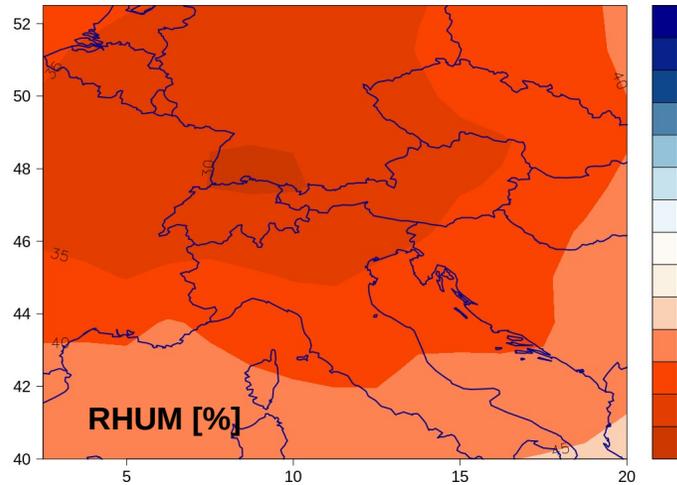

Zentroid

Type 17 – V-Component of Wind

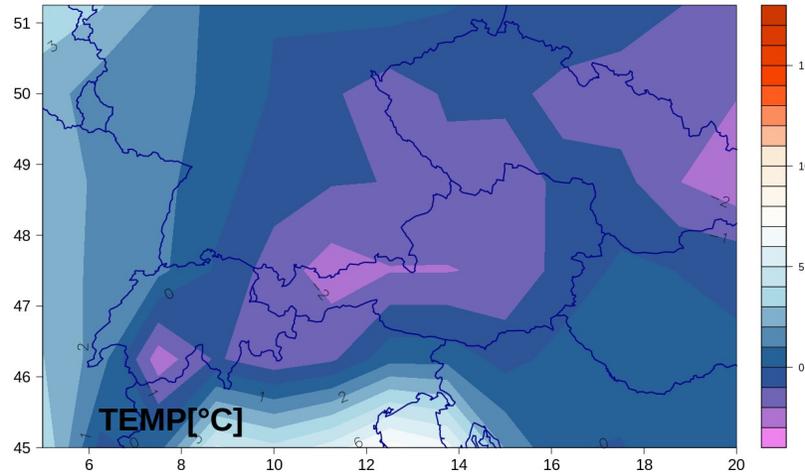

Zentroid

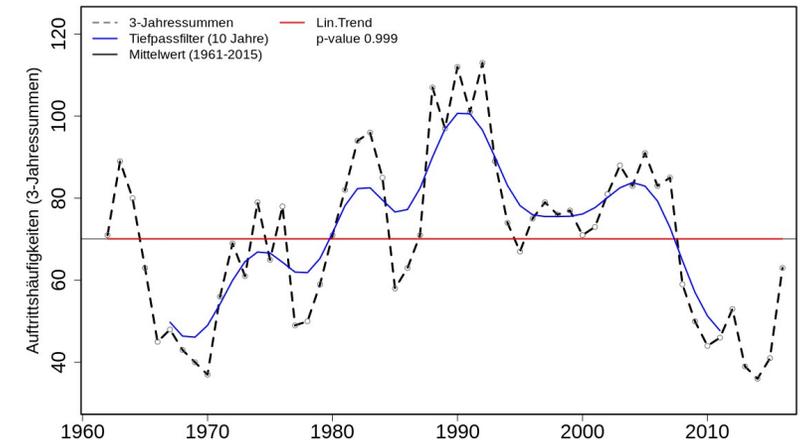

Type 17 – Relative Humidity

Type 17 – Temperature

Type 17 – Frequency

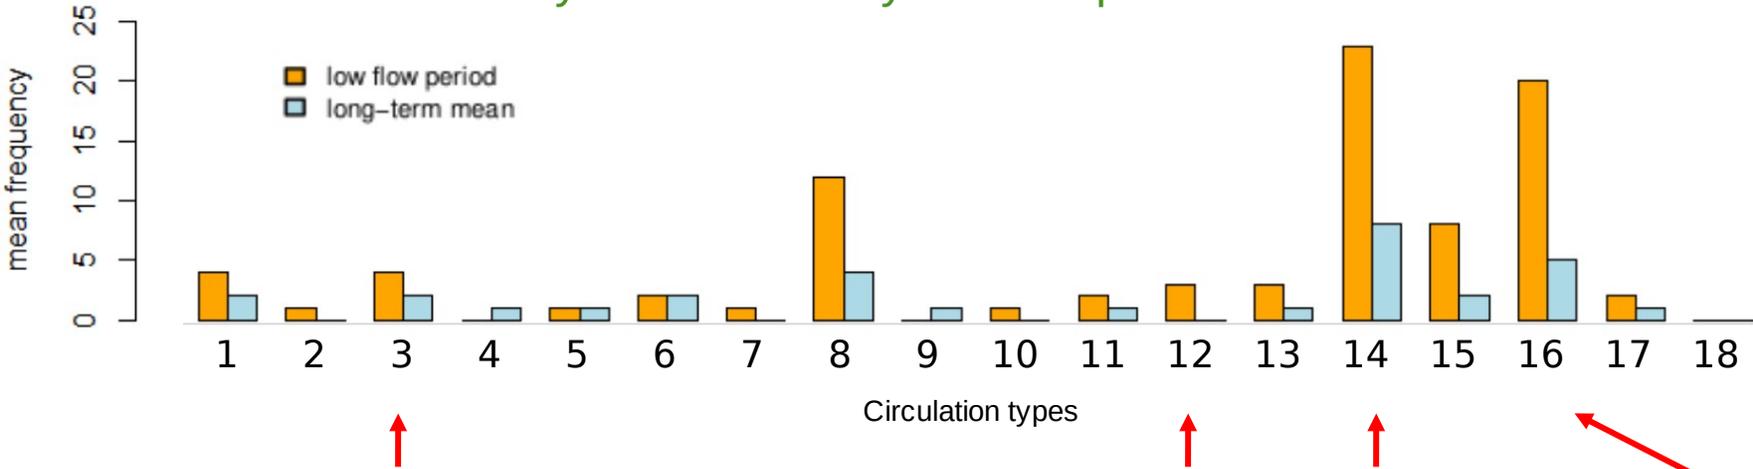

Drought relevant CT 17 mean fields from all single days 1961-2015: mean sea level pressure [hPa] (MSLP), U- and V-Wind component [m/s] at 700 hPa, relative humidity [%] (RHUM) at 700 hPa and Temperature [°C] (TEMP) at 2m. Trend analysis (confidence level 95%), moving 3-year occurrence frequencies, smoothed time series (Gaussian low-pass filter over 10 years) and linear trend.

4 Implications for low flow

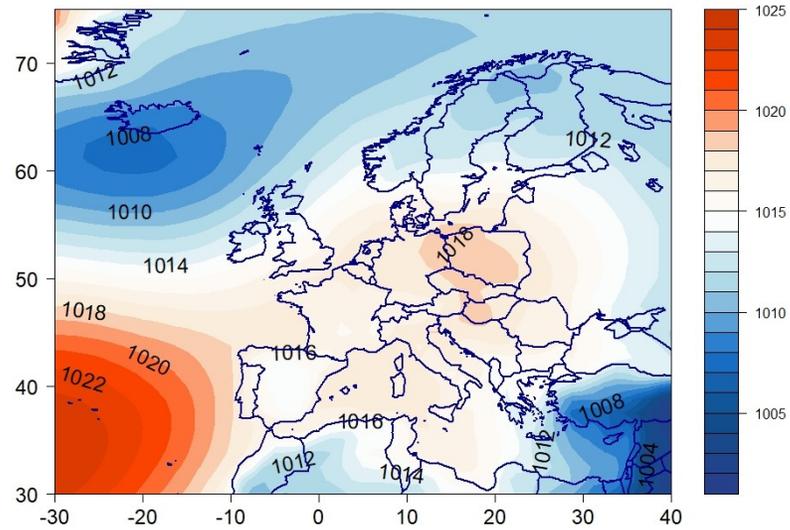

87 consecutive days - mean discharge below the 5th percentile 7.1 [m³/s] of the long-term mean.

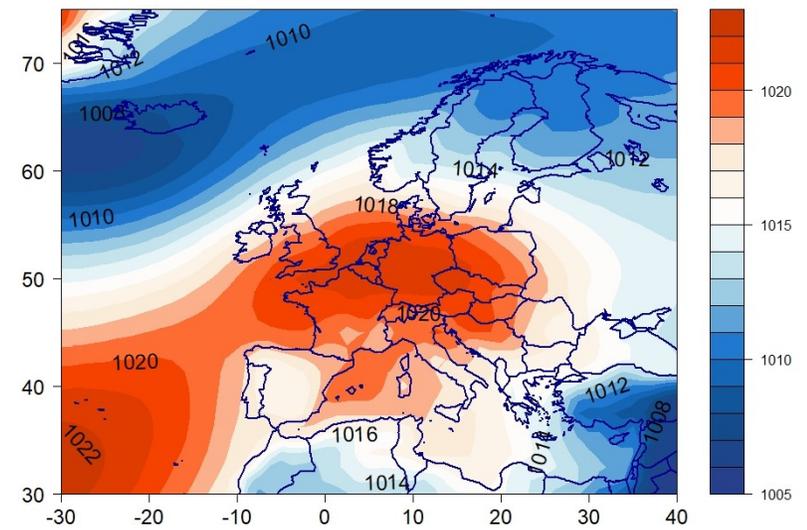

Isar river Germany Bavaria 6. July – 30. September 1962

Circulation type 14 - Mean sea level pressure

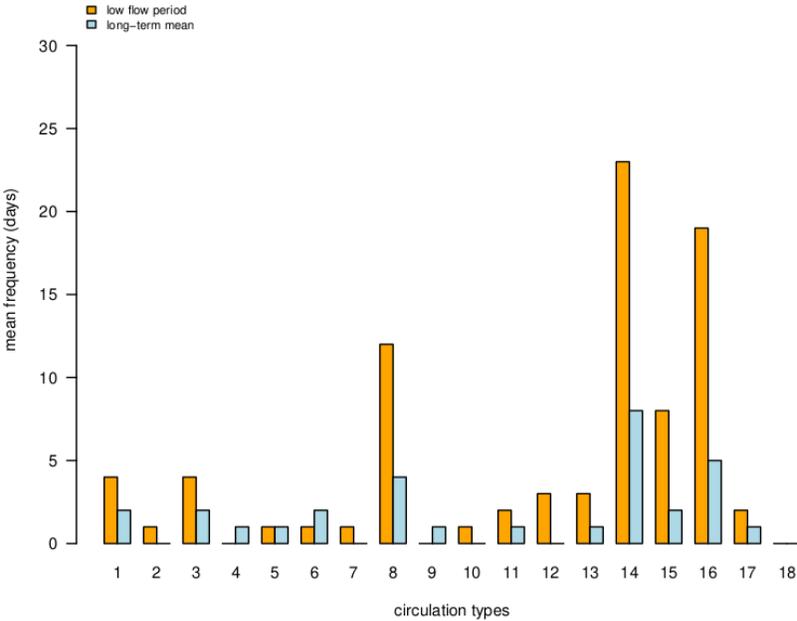

Circulation type 16 - Mean sea level pressure

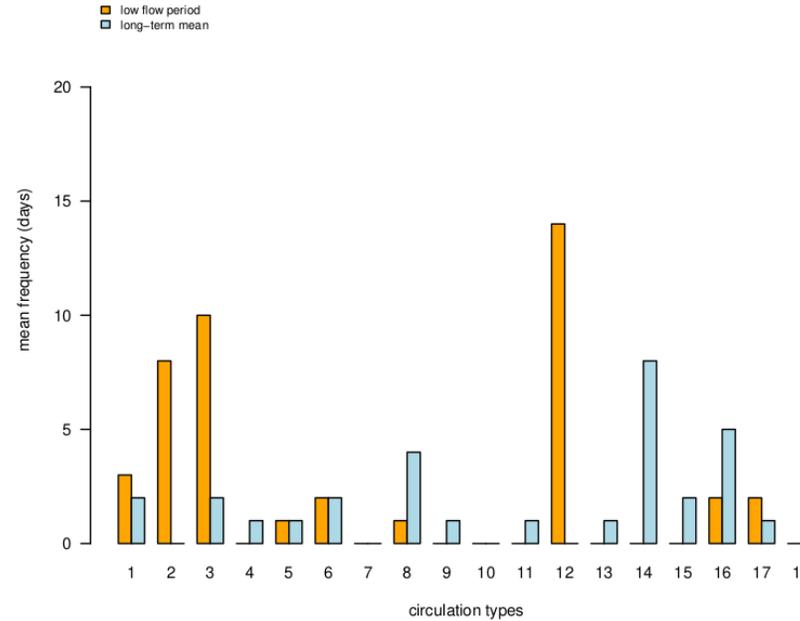

4 Implications for low flow

Circulation type frequencies during summer low-flow periods

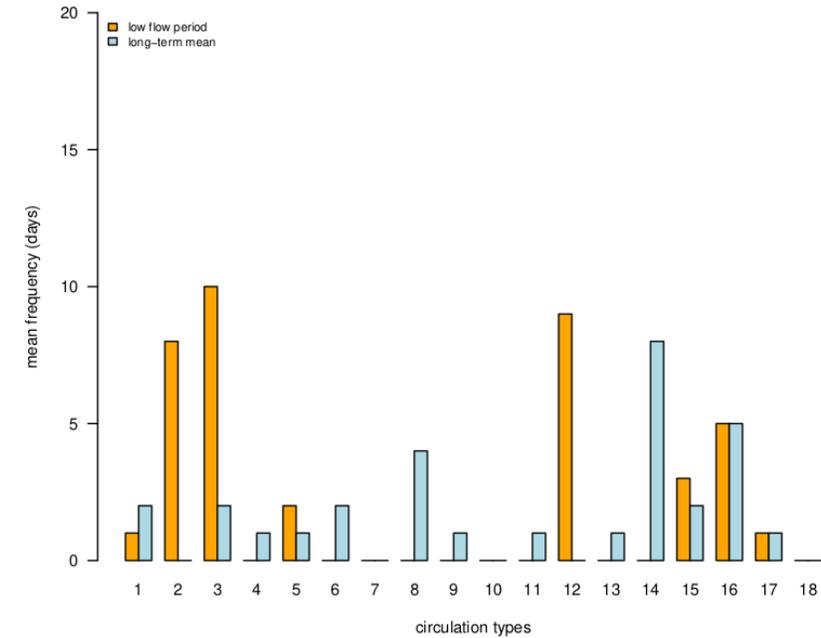

Period 1 – Start: 1962-07-08 , 85 days

Period 2 – Start: 1963-04-02 , 44 days

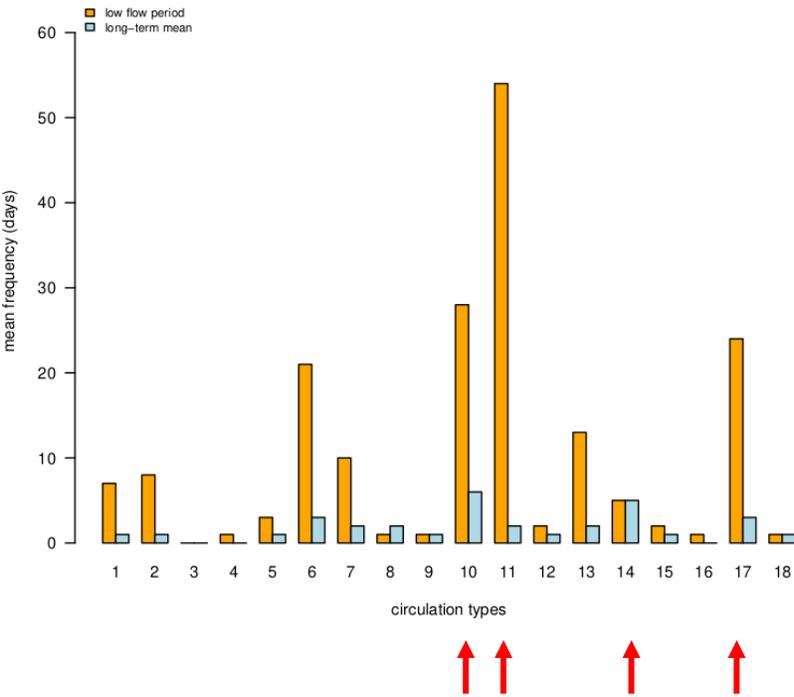

Period 3 – Start: 1969-04-03 , 41 days

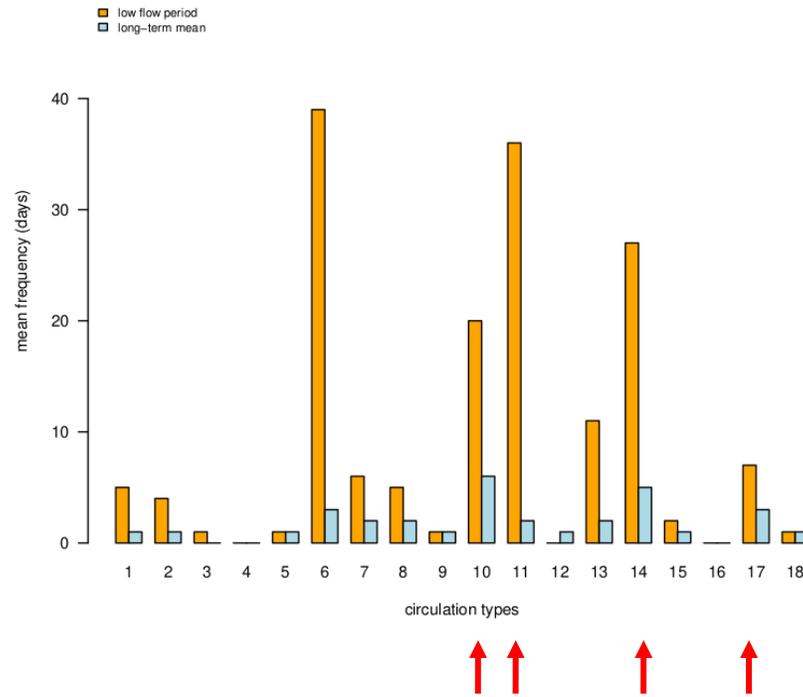

4 Implications for low flow

Circulation type frequencies during winter low-flow periods

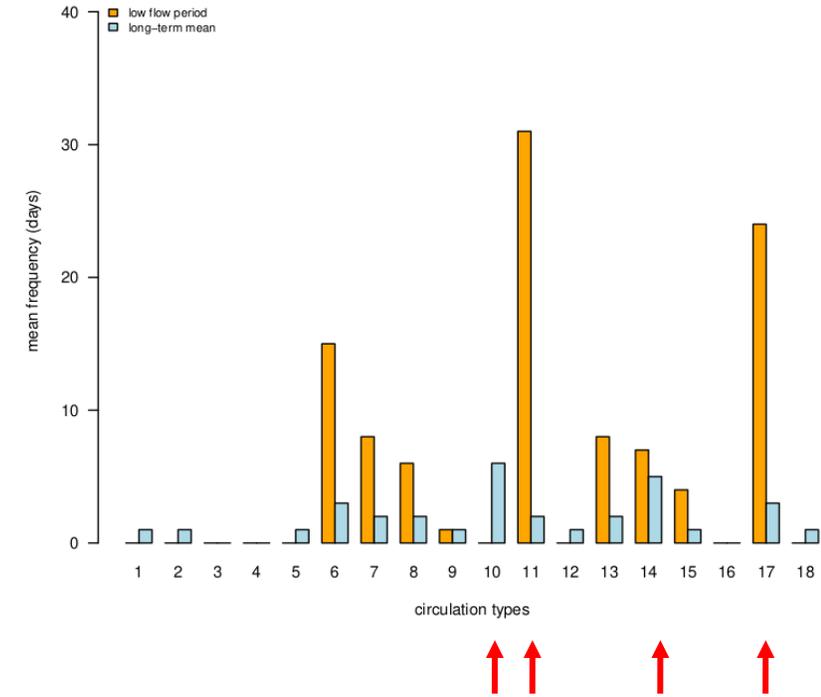

Period 1 – Start: 1962-10-01 , 182 days

Period 2 – Start: 1971-10-18 , 167 days

Period 3 – Start: 1970-12-04 , 106 days

5 Future Changes

Frequency changes

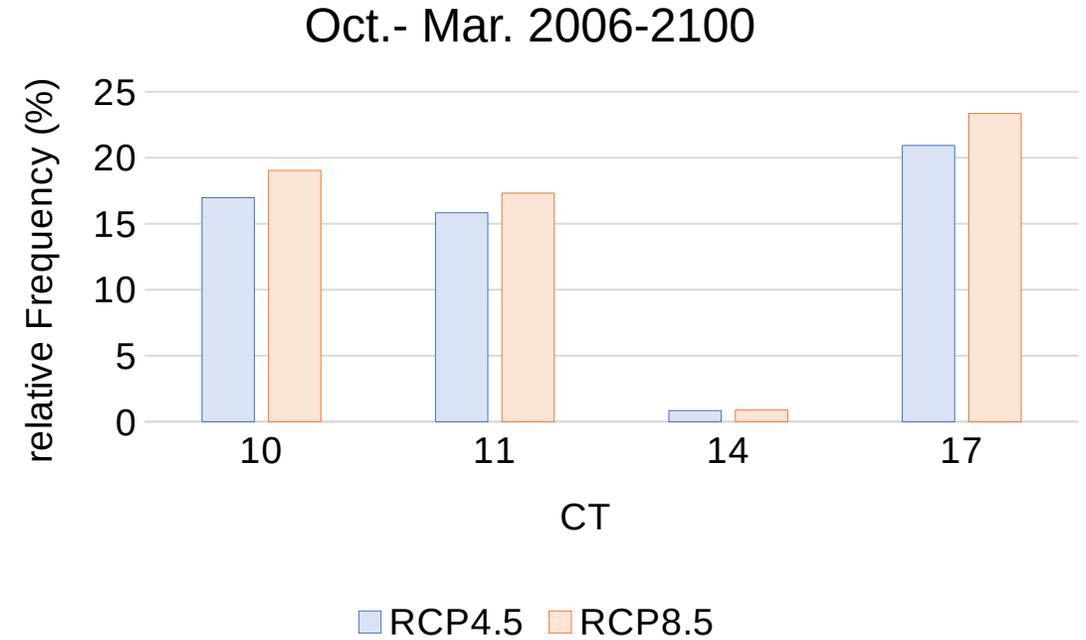

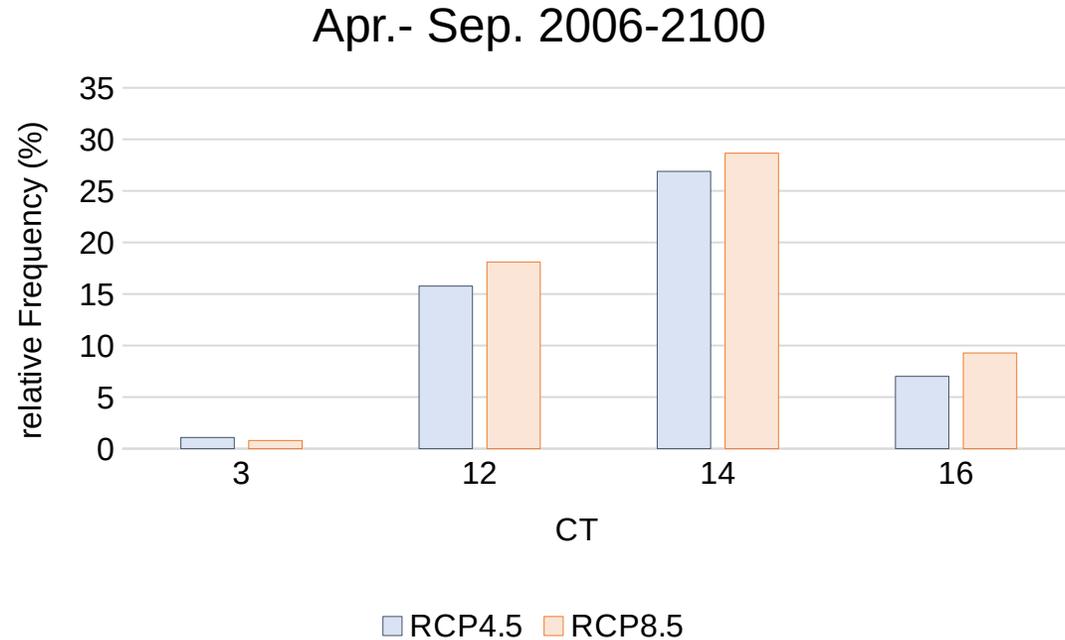

of drought-relevant circulation types in the regional climate models (RCP8.5) between the control period (1971-2000) and the projection periods (2031-2060 and 2071-2100)

1. Projection Period 2031-2060	April-September				October-March

6 Summary and Conclusion

- ♦ **drought-relevant circulation types** have been identified via advanced circulation type classification for the period 1961-2017
- ♦ projection of circulation types on RCM-output:
 - ♦ **frequency changes** until 2100 (showing increasing and decreasing trends for specific types)
 - ♦ changes appear more **distinct after 2071**
 - ♦ higher frequencies of drought relevant types **under RCP8.5**
 - ♦ varying **changes in persistence** of types
 - ♦ **within-type changes** include intensified anticyclonic conditions, increasing temperatures, reduced humidity
- ♦ drought relevant **types are related to periods of low flow** in the Isar river:
 - ♦ in summer mainly types with elongated Azores high pressure ridge
 - ♦ in winter mainly anticyclonic types centred over southern and central Europe
 - ♦ overall increasing frequencies of low flow relevant types until 2100 in summer
