

Manifestation of Socio-Economic Influences in Discharge Patterns

Jörg Uwe Belz

Bundesanstalt für Gewässerkunde
Federal Institute of Hydrology (D)

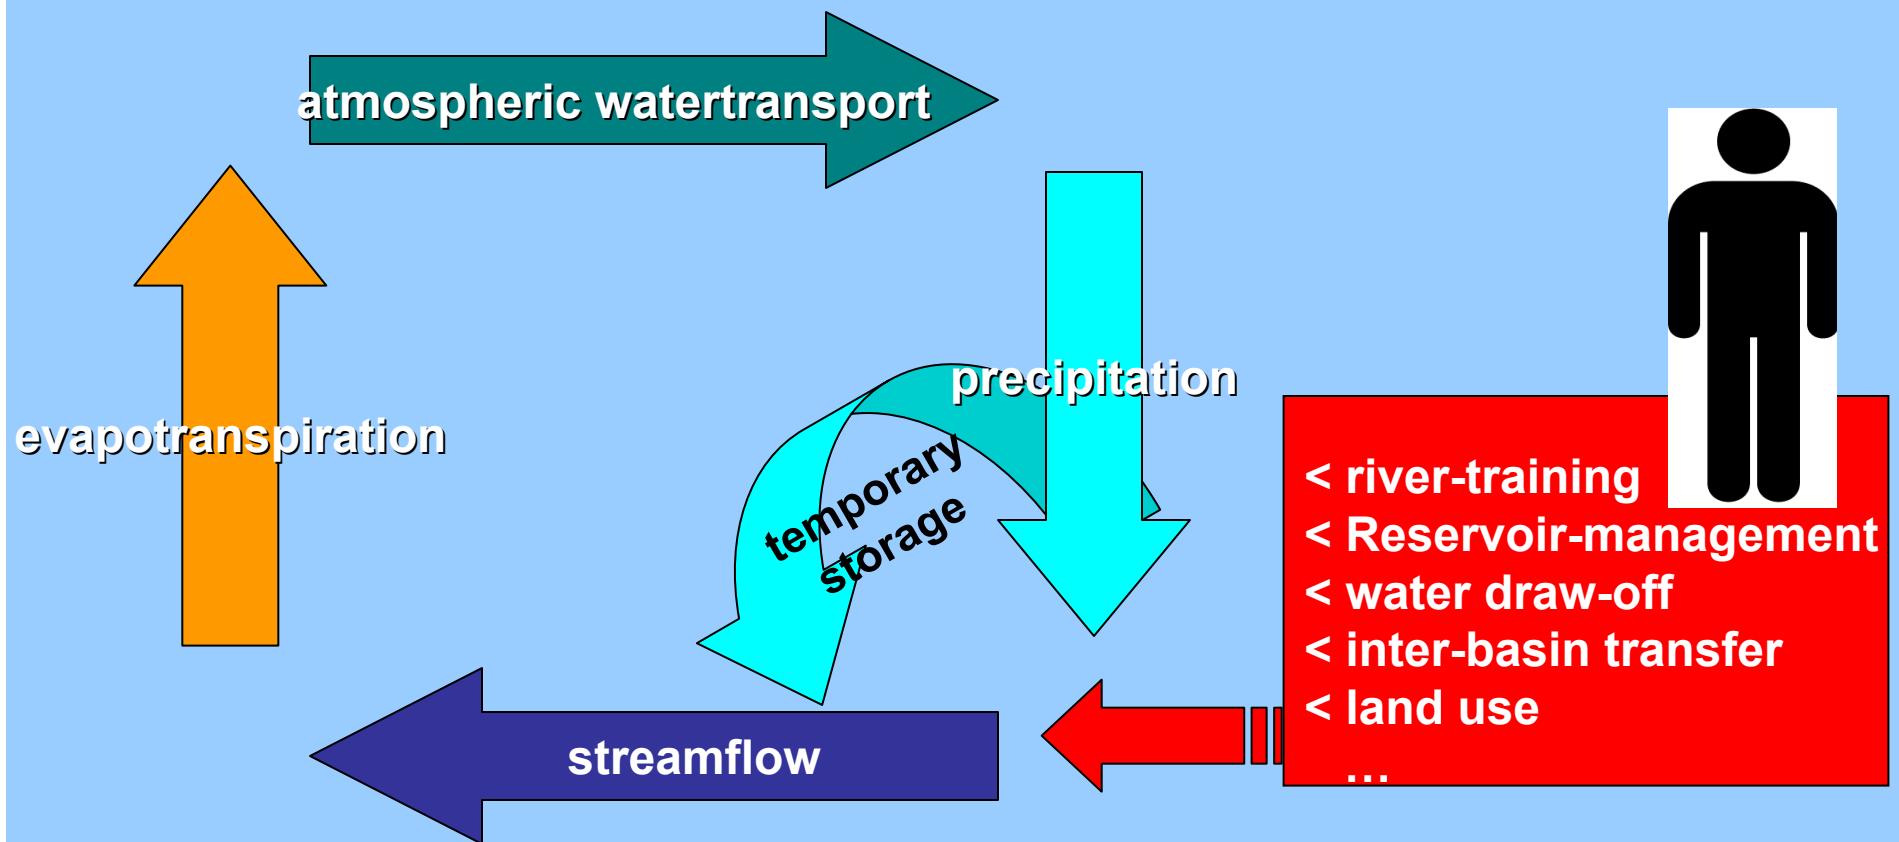

Socio-economics...

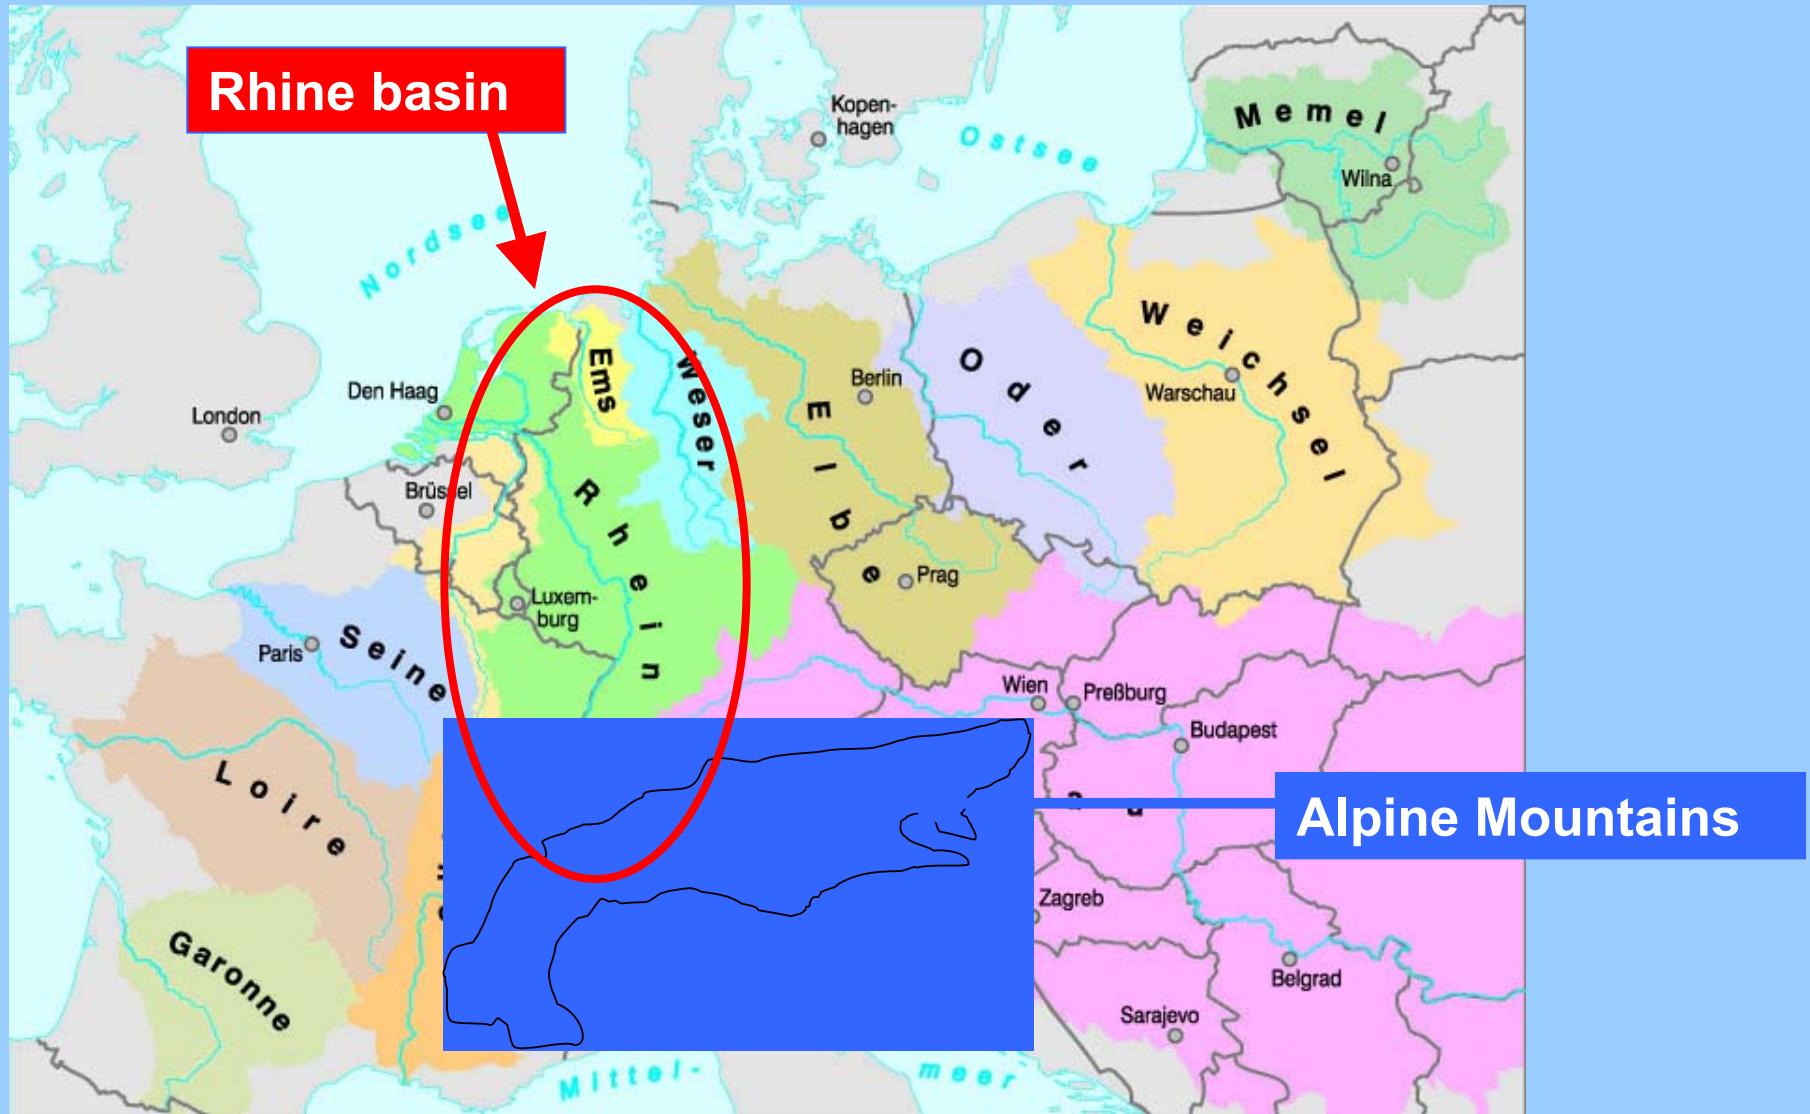

...focus on the interactions and interdependencies of politics, society and economics...

...thus „**socio-economic influence**“ is a complex of developments, like an indirect force triggering various anthropogenic processes, which may lead to substantial modification of elements of the natural water-cycle.

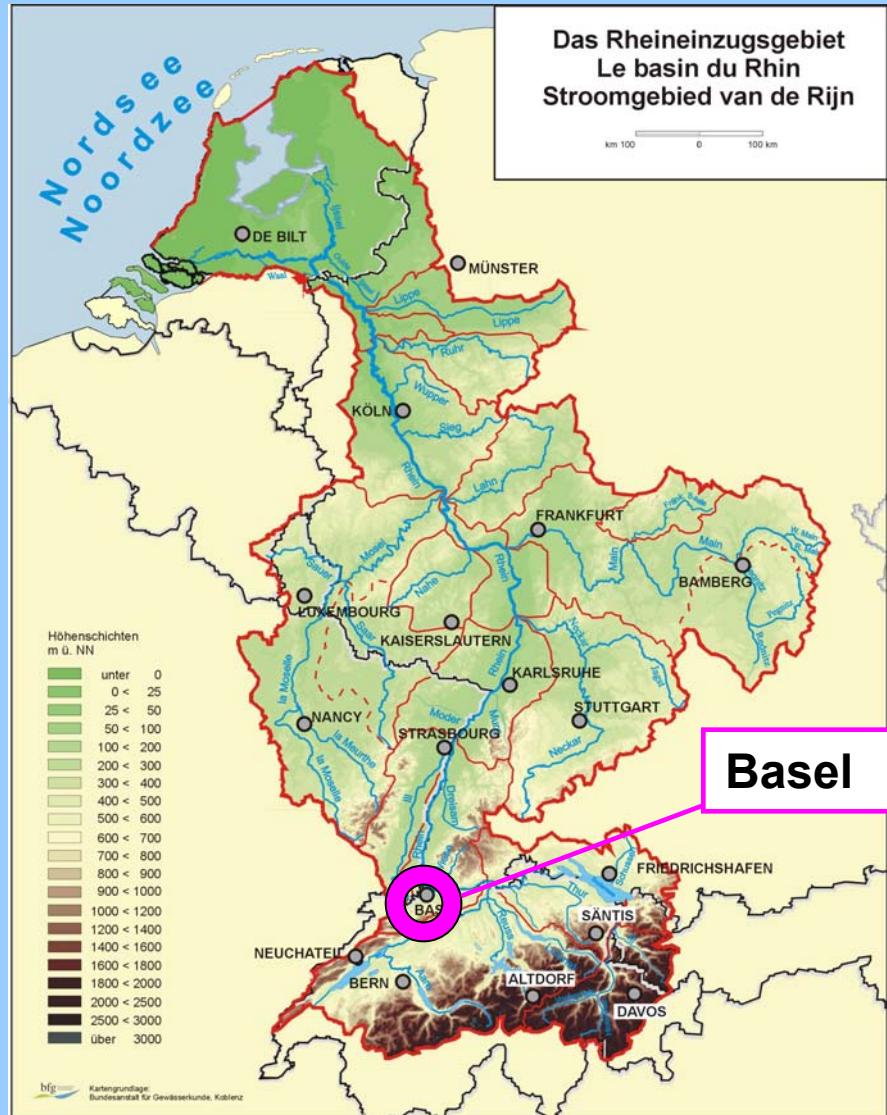

Hydrologic cycle and the anthropogenic impact on streamflow characteristics

Major river basins in Europe

River Rhine: Basin characteristics

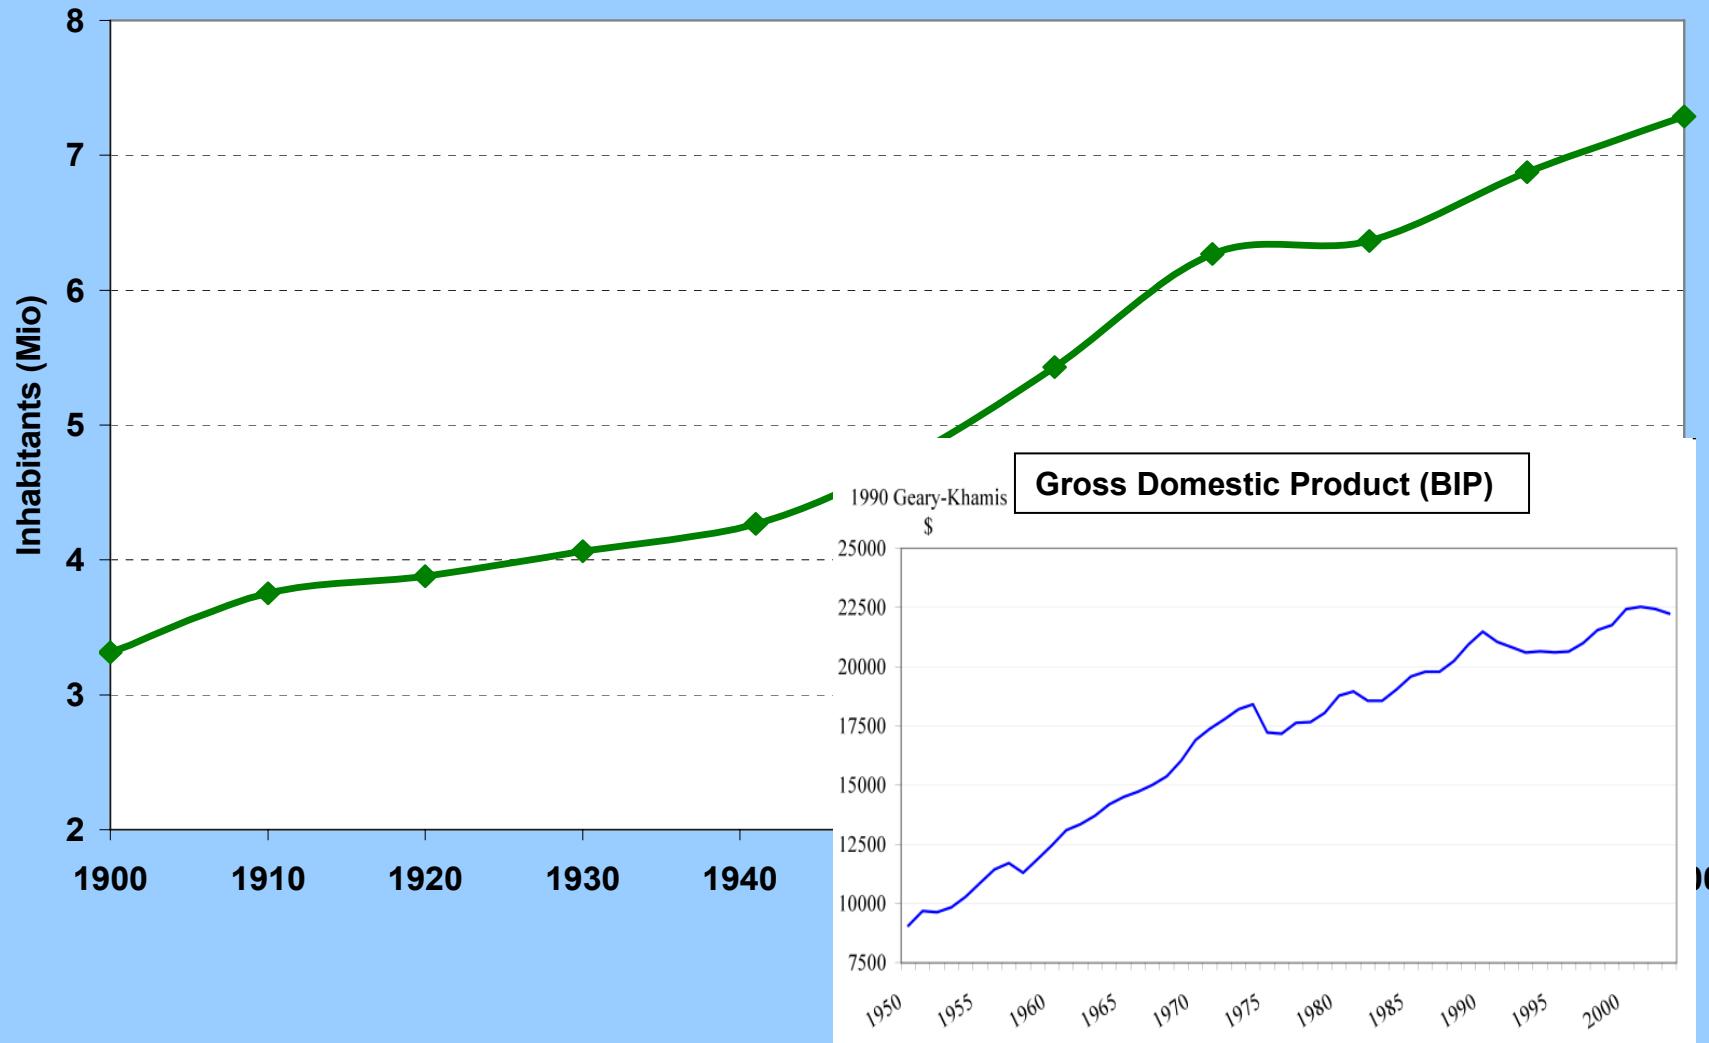

- $A_{Eo} \sim 197.000 \text{ km}^2$
- $\sim 58 \text{ Mio. inhabitants}$
- **9 riparian countries**
- **river length:** $\sim 1238 \text{ km}$
- **primary flow-parameters near the mouth:**
 - NNQ** $\sim 600 \text{ m}^3/\text{s}$
 - MQ** $\sim 2.500 \text{ m}^3/\text{s}$
 - HHQ** $\sim 12.000 \text{ m}^3/\text{s}$

Socio-economic Dynamics in Switzerland

Switzerland: Demographic Development

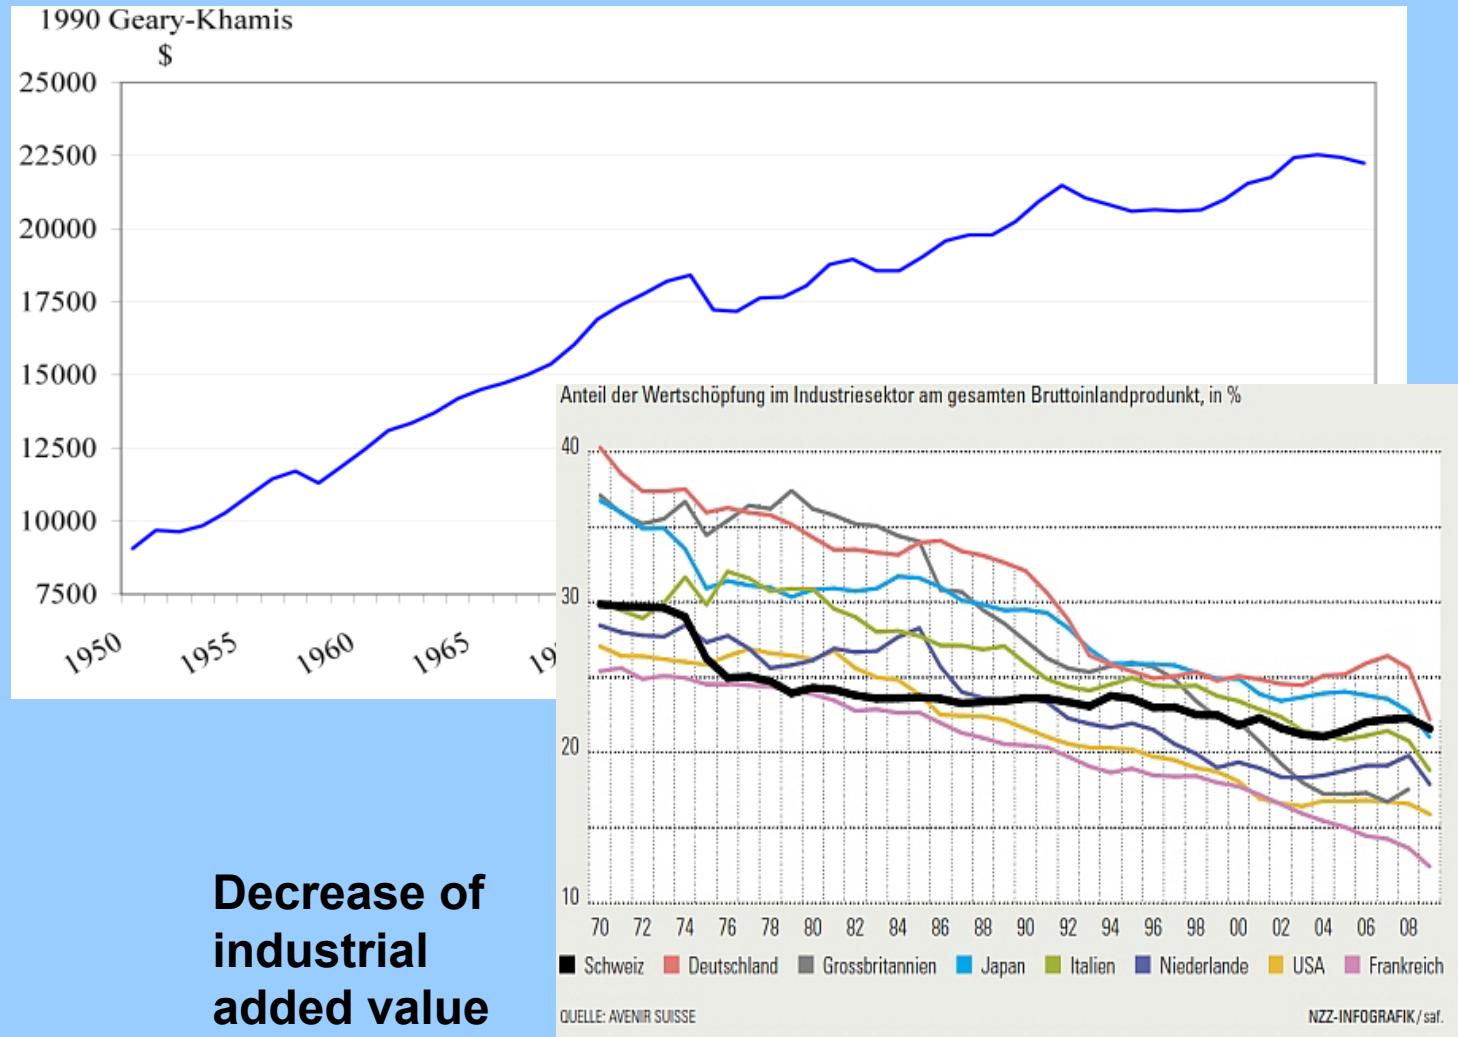

(data: BFS CH)

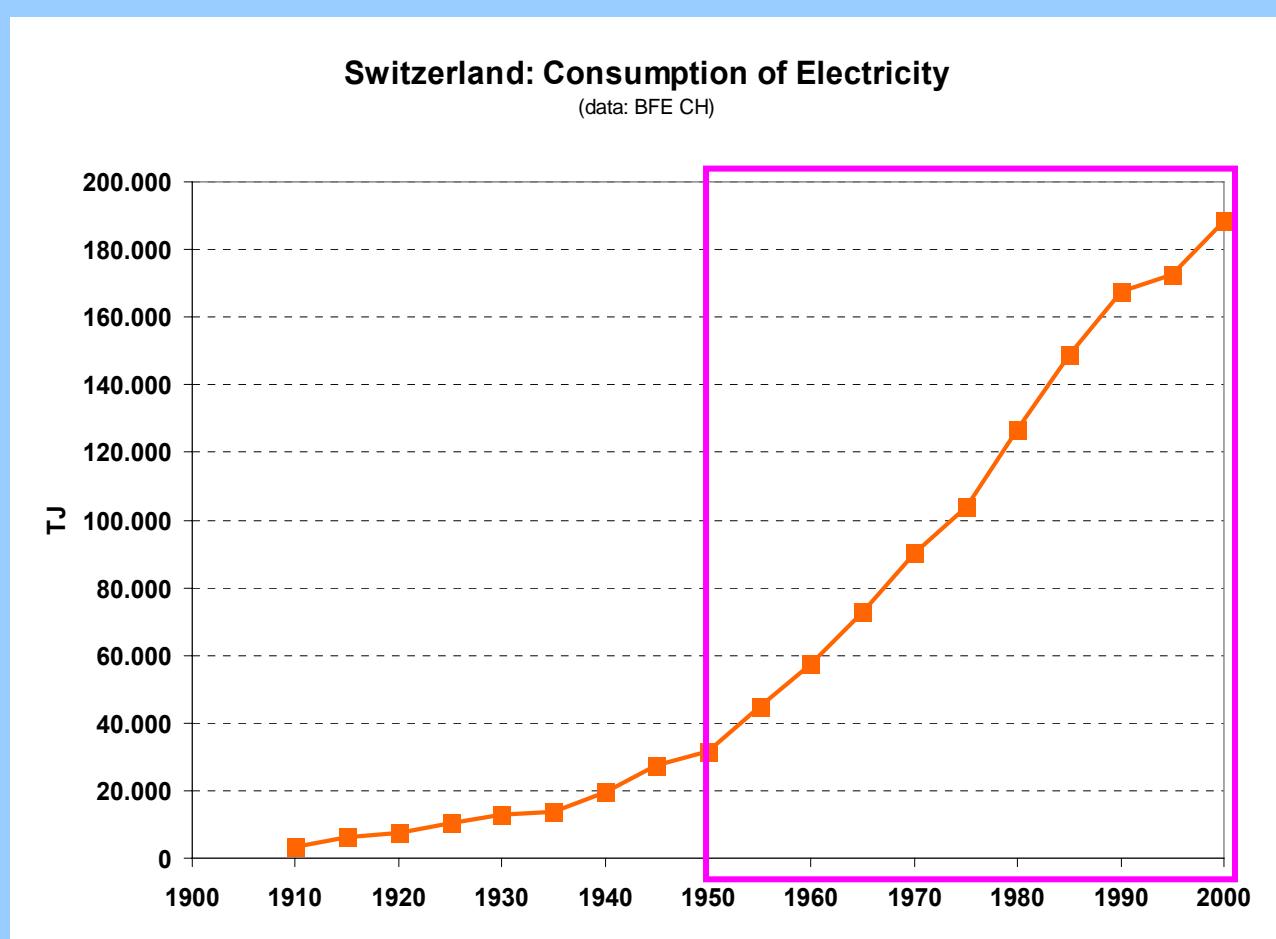

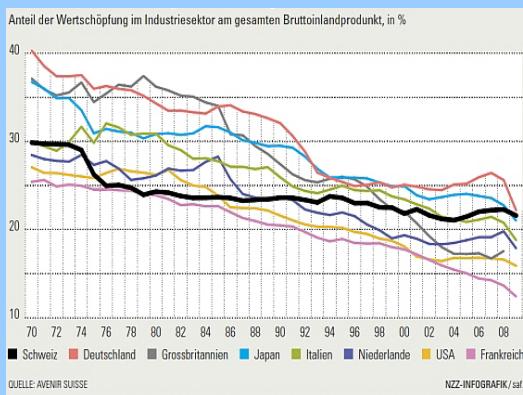

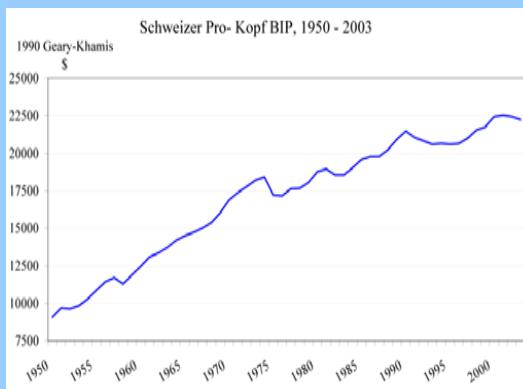

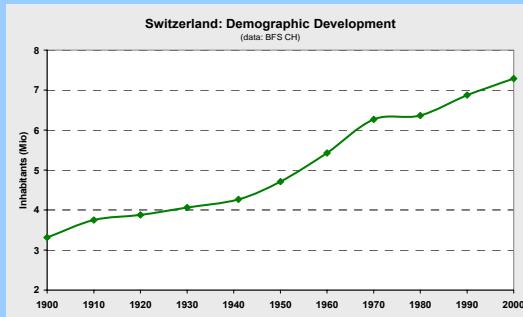

Socio-economic Dynamics in Switzerland

**Increasing
Gross
Domestic
Product**

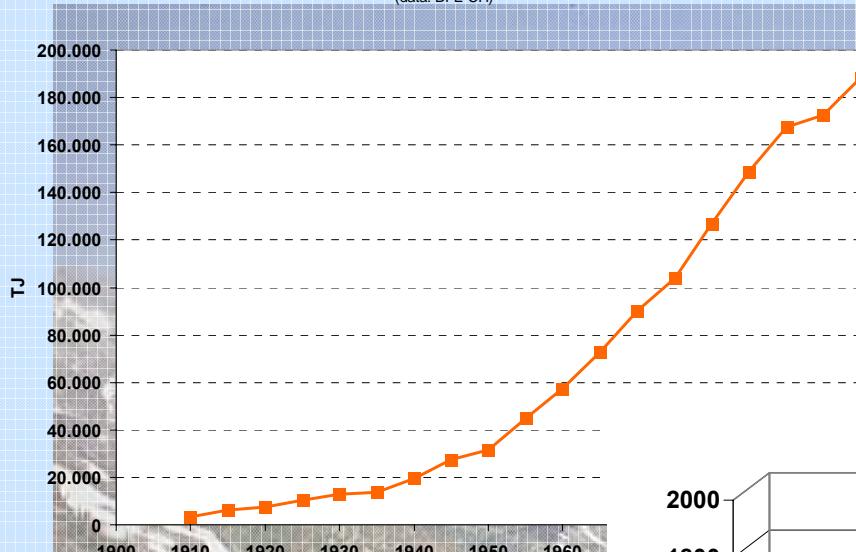

Electricity: A Vital Need in Modern Societies

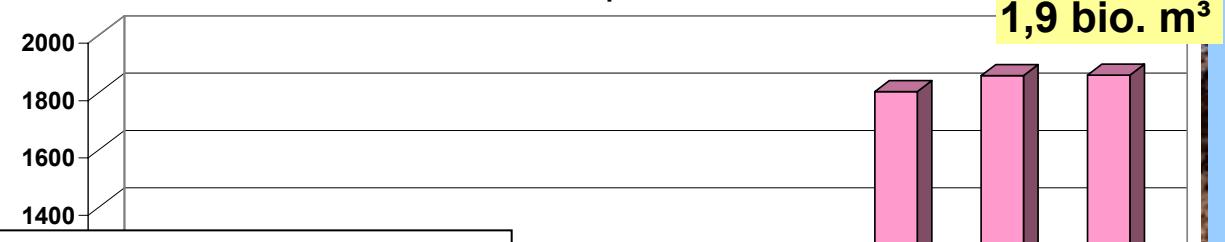

Reservoir-Building as result of socio-economic needs

Switzerland: Consumption of Electricity

(data: BFE CH)

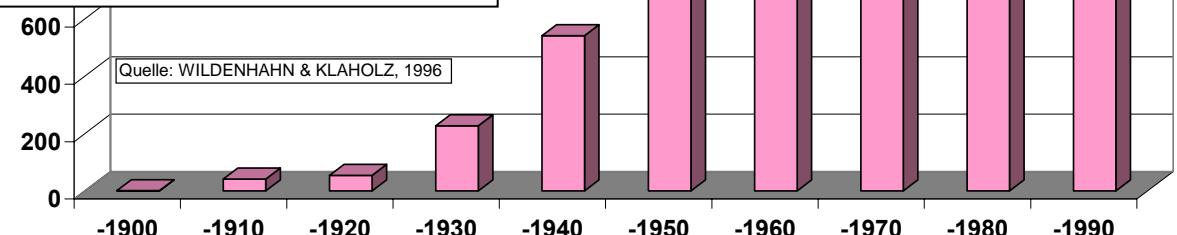

Chronologically cumulated capacity of large reservoirs
in the Rhine basin upstream of Basel

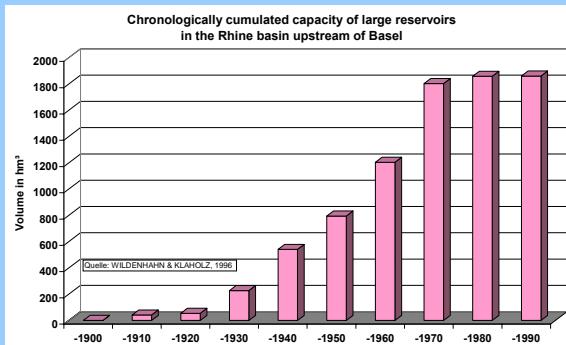

1,9 bio. m³

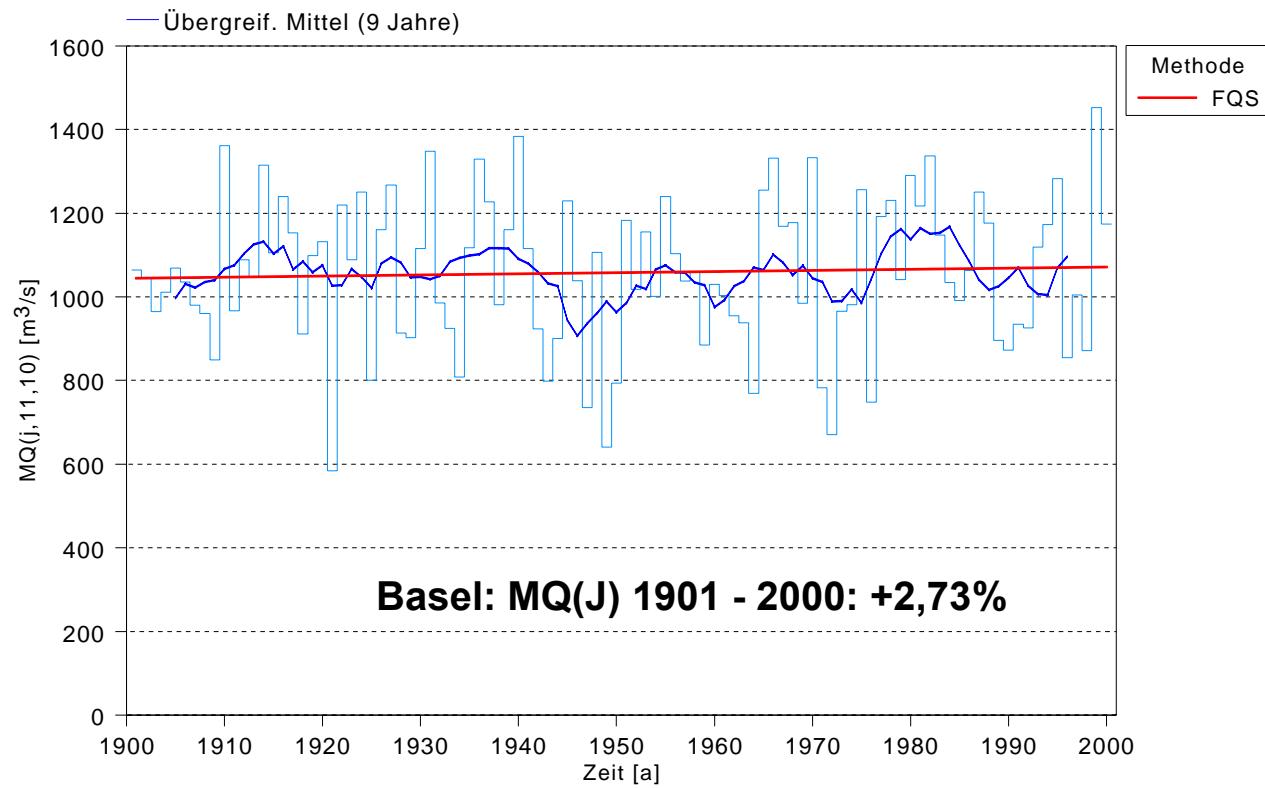

Reservoir-building to meet the
demand of electricity is limited by
disposable sites (valleys)

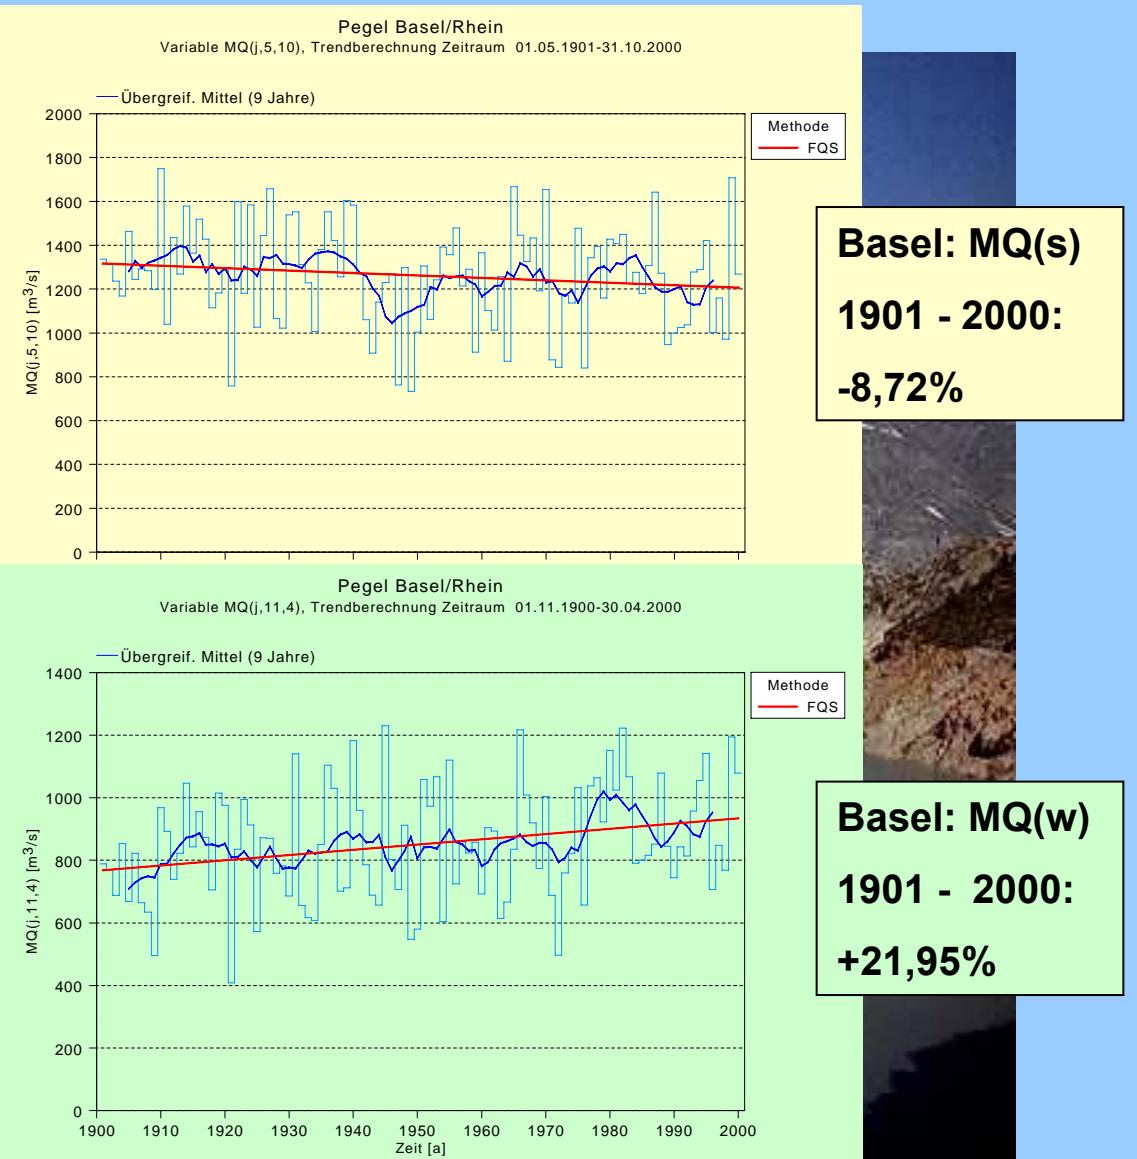

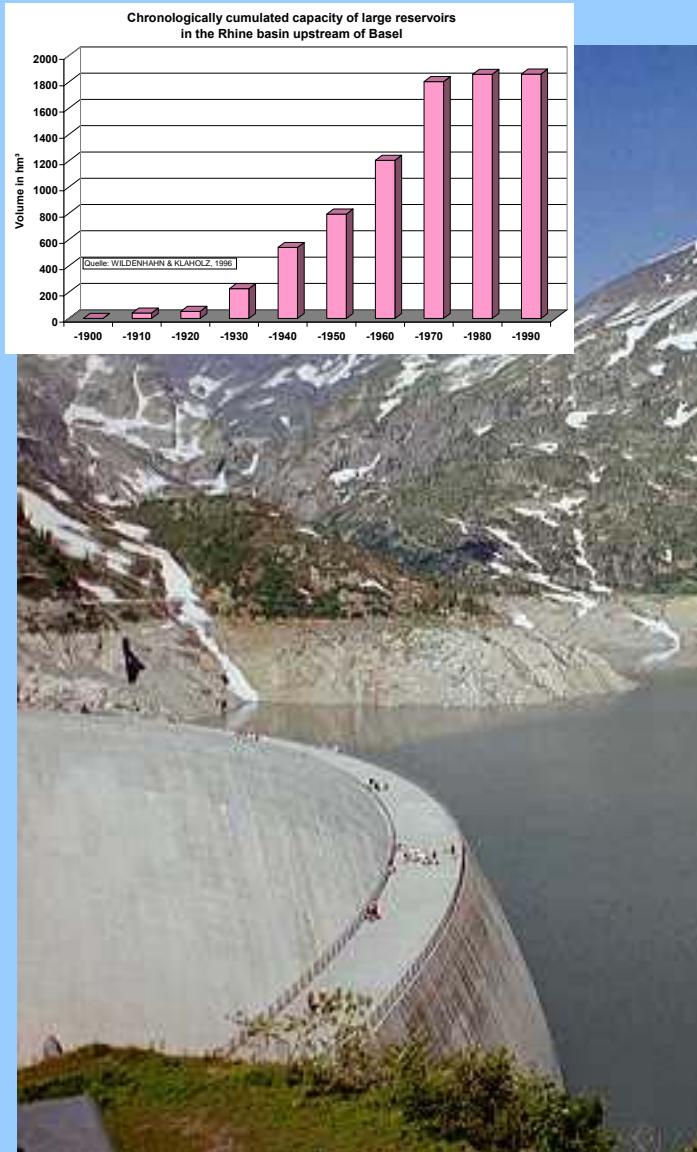

Changes of flow-regime: Seasonal Redistribution

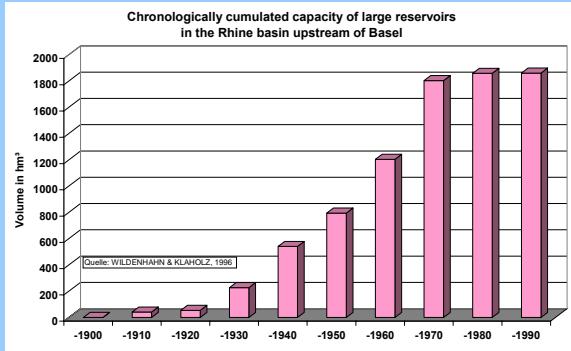

Pegel Basel/Rhein
Variable MQ(j,11,10), Trendberechnung Zeitraum 01.11.1900-31.10.2000

Changes of flow-regime: Seasonal Redistribution

Changes of flow-regime: Seasonal Redistribution

Power-storage: Reservoir-management with seasonal redistribution-effects

summer → winter

Reservoirs in the Alpine region (mainly run for energy-production purposes) have seasonal redistributing effects:

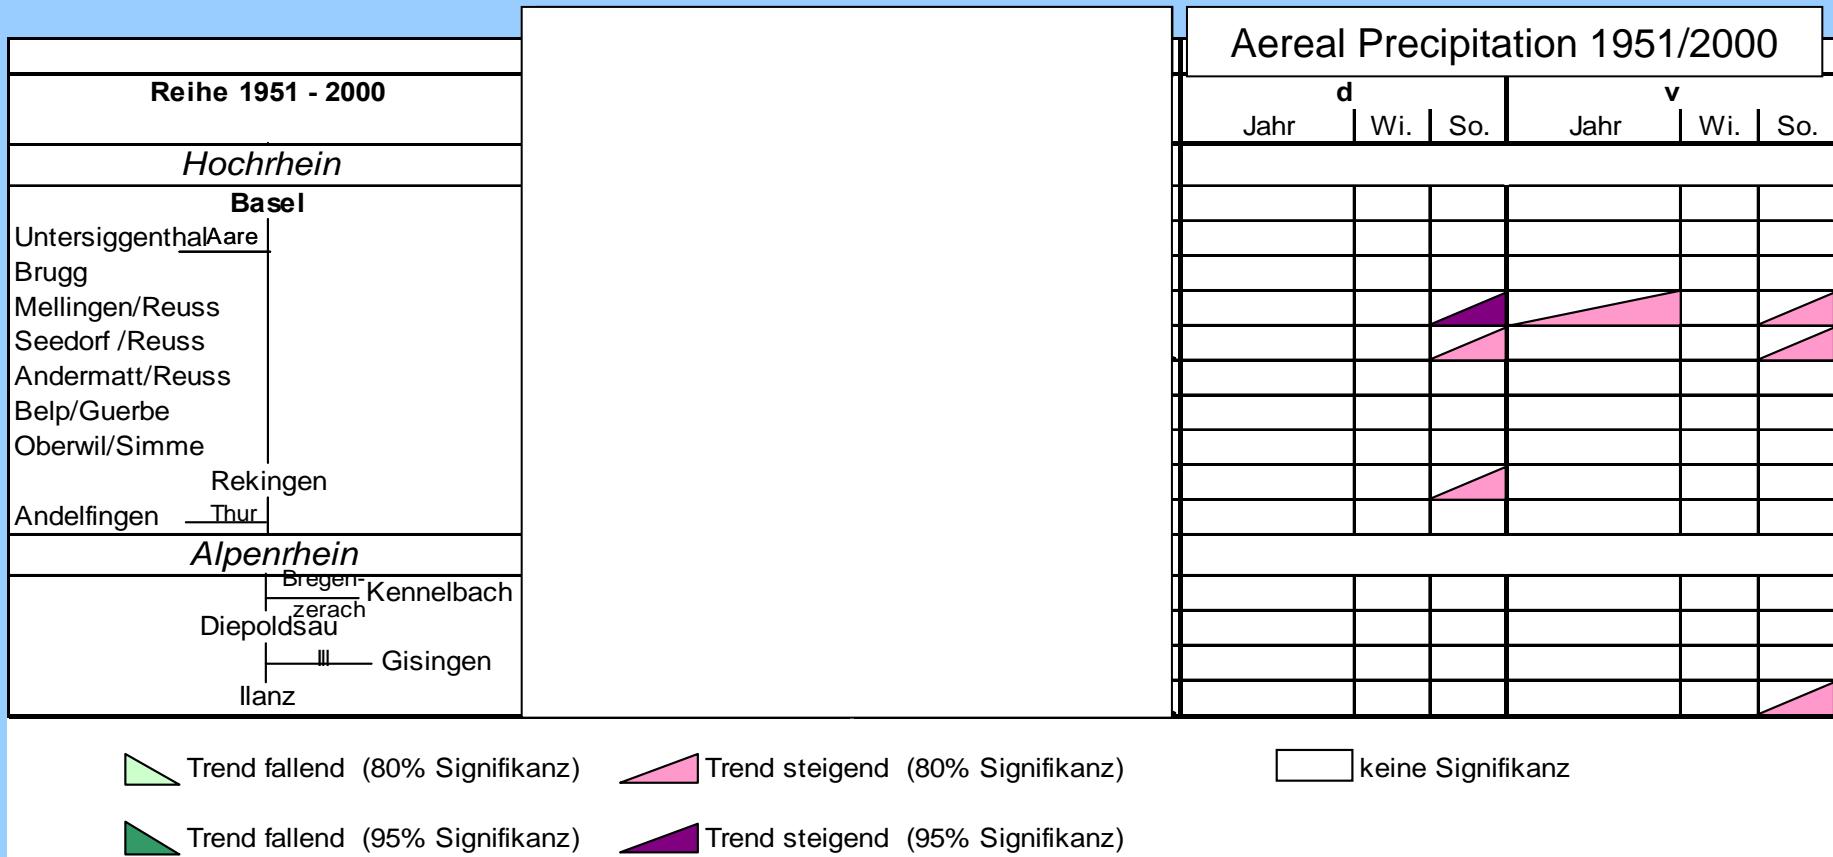

- **collecting water during surface-water affluence in summer**
- **releasing water during frost-induced low-flow-season in winter**

Upstream Basel: total reservoir-capacity 1,9 bio. m³ p.a.

Assumption: Seasonal transfer-volume 50% → ~60 m³/s per season

(Basel: MQ(w) 1901 – 2000: +167 m³/s)

Changes of flow-regime: Variability of Discharge

Mean error
„fluctuation around the average“

$$d = \frac{1}{n} \sum |x_i - \bar{x}|$$

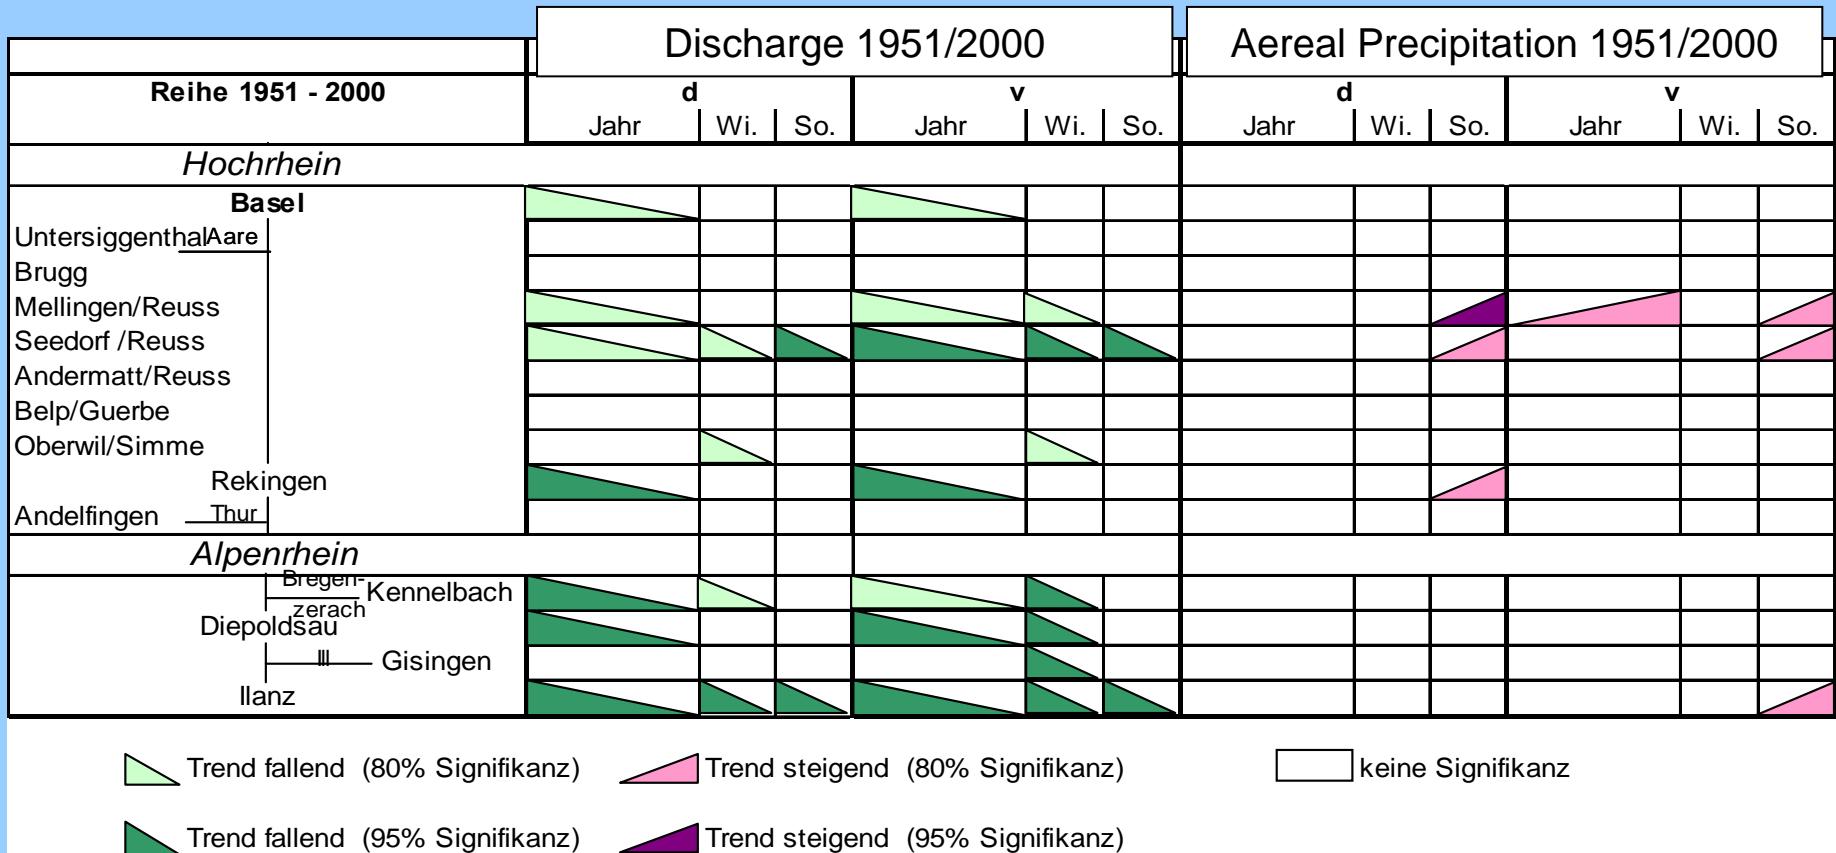

n = sample size
 x_i = (monthly-)solitary value of the sample
 \bar{x} = arith. mean of the sample

Robust variation-coefficient
„span of the more frequent extreme-values vs. median“

$$v = (Q_{95} - Q_5) : Me$$

Q_{95} = 95%-quantile of annual/seasonal series
 Q_5 = 5%-quantile of annual/seasonal series
 Me = median of annual/seasonal series

Changes of flow-regime: Variability of Discharge

„fluctuation around the average“

$$d = \frac{1}{n} \sum |x_i - \bar{x}|$$

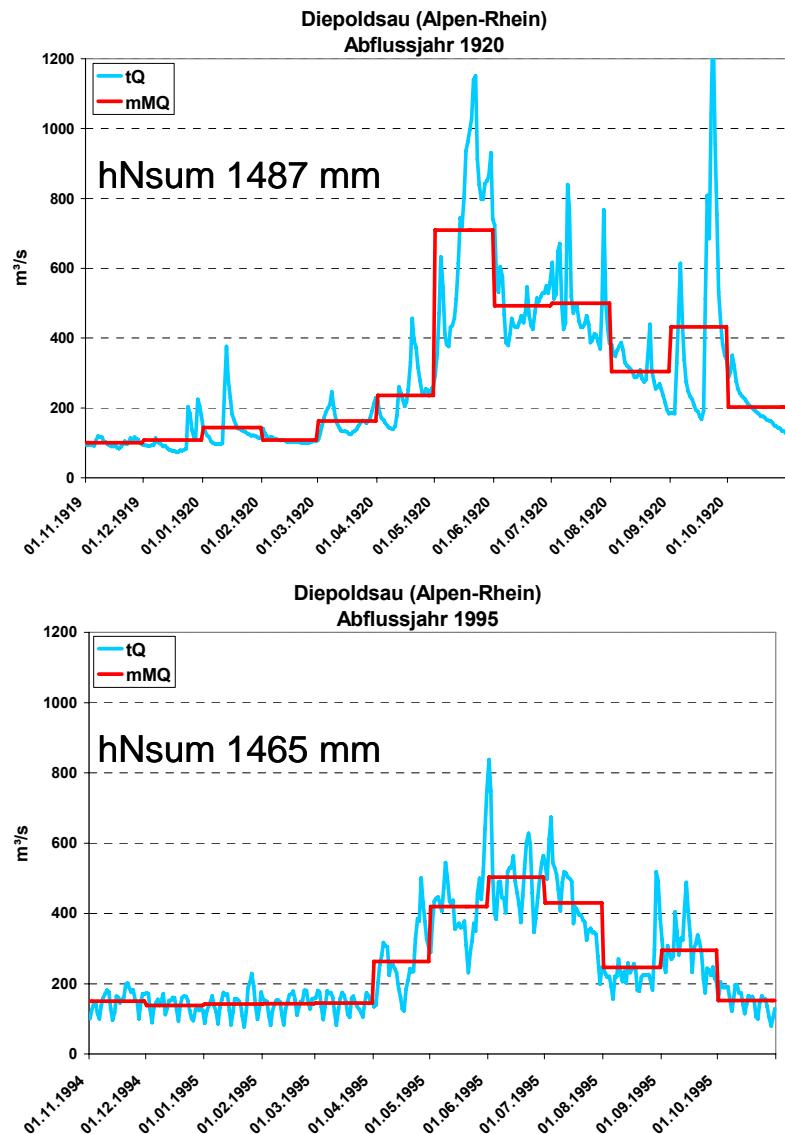

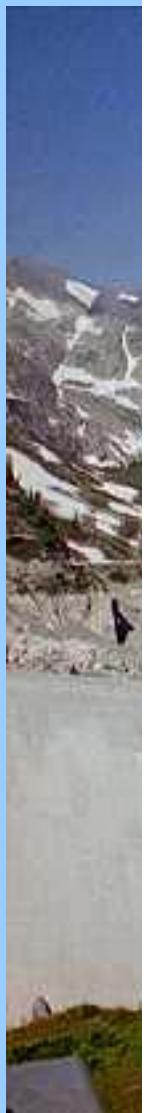

n = sample size
 x_i = (monthly-)solitary value of the sample
 \bar{x} = arith. mean of the sample

„span of the more frequent extreme-values vs. median“

$$v = (Q_{95} - Q_5) : Me$$

Q_{95} = 95%-quantile of annual/seasonal series
 Q_5 = 5%-quantile of annual/seasonal series
 Me = median of annual/seasonal series

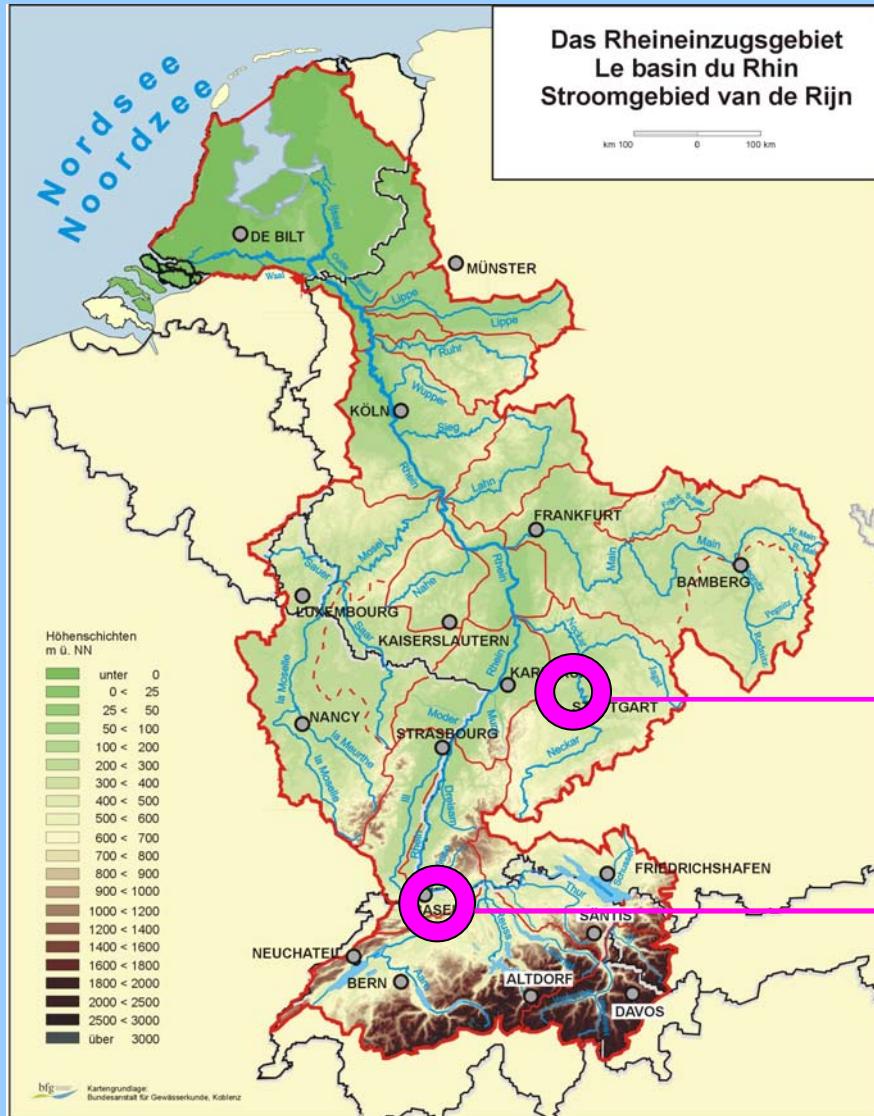

Changes of flow-regime: Variability of Discharge

**Reservoir-management
with reducing effects
on annual and intra-annual
flow variability**

**...one important,
but not the only responsible
process to enforce
equalizing runoff**

Socio-Economic Influence on Runoff-Characteristics: River Neckar

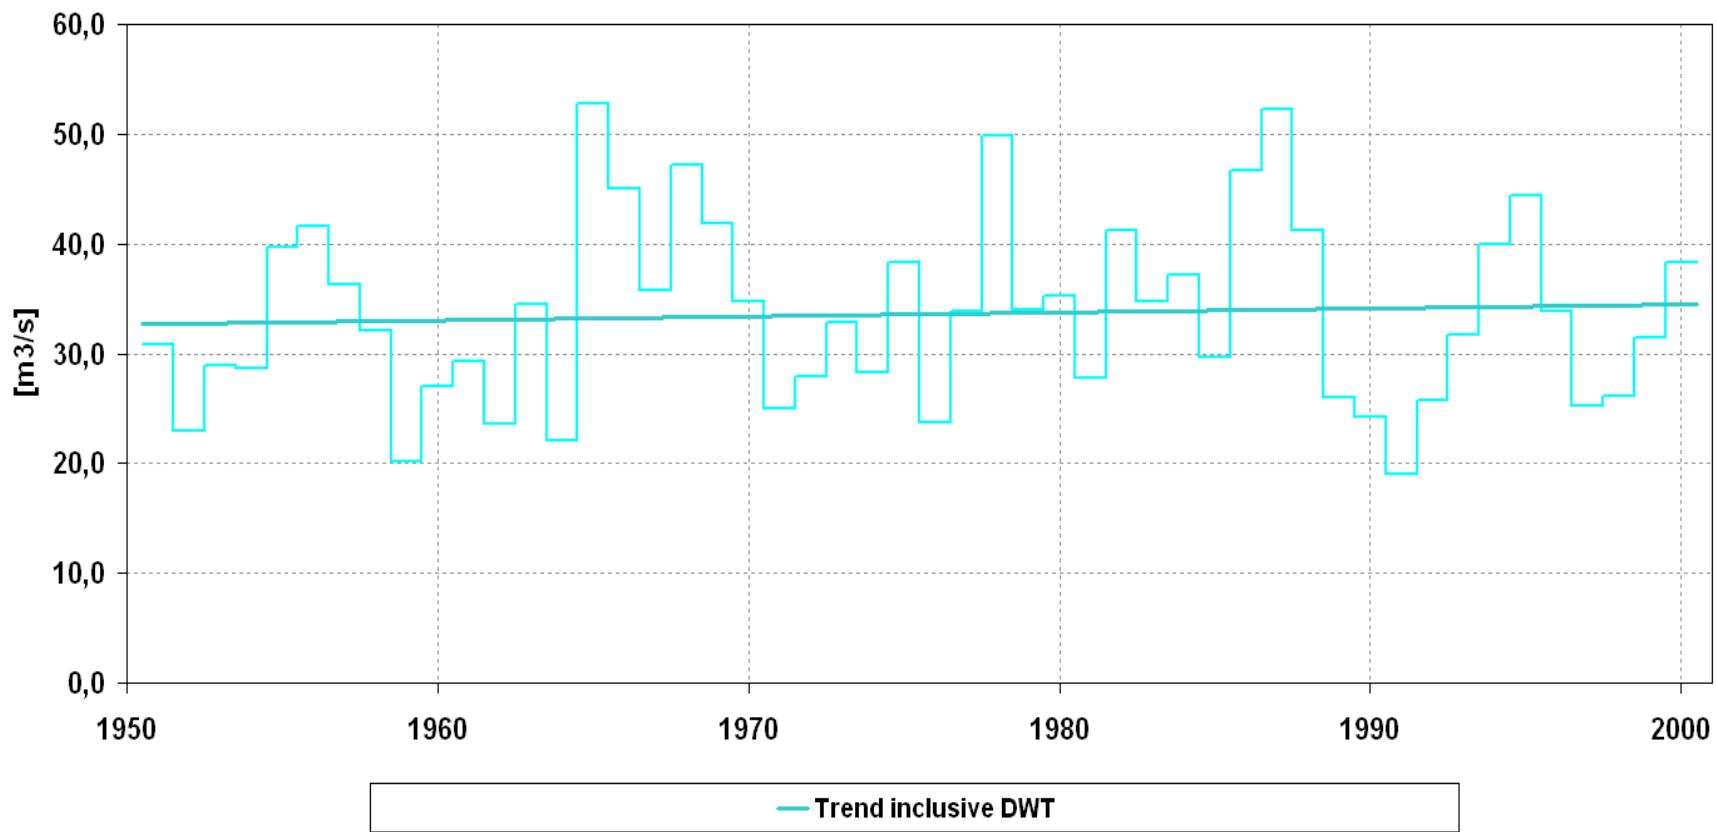

Lauffen

**Contradictions / disagreements of the flow- and the precipitation-dynamics in the last 50 years in large regions of the catchment:
in wide areas slight increase of precipitation versus moderate decrease of runoff**

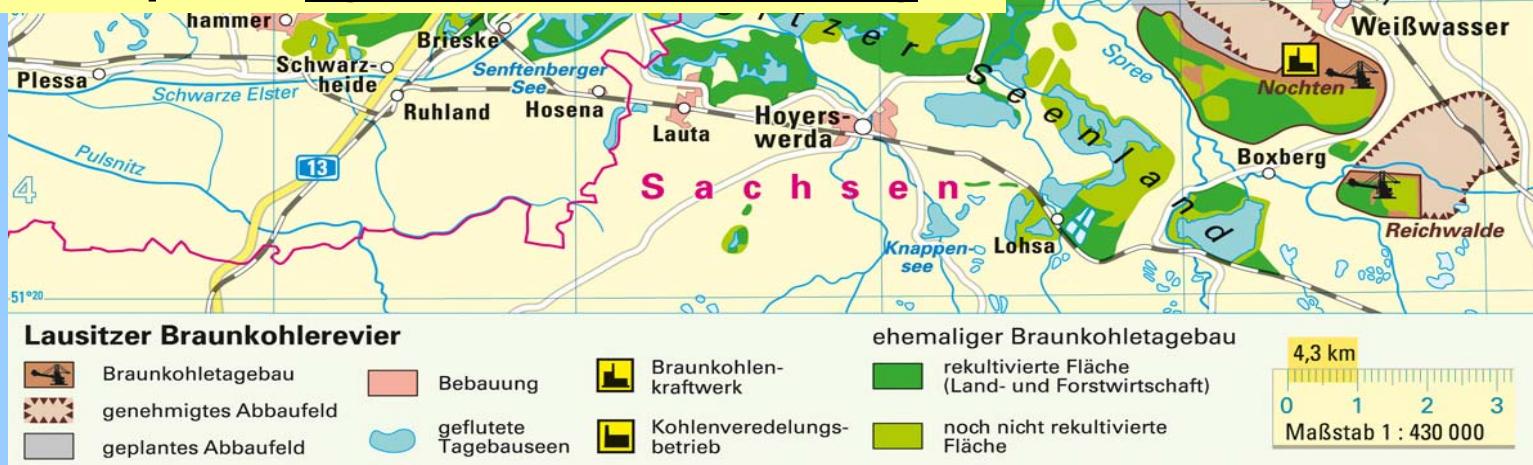

Analýza Qmin7d
říjního roku

Socio-Economic Influence on Runoff: Lignite and Politics

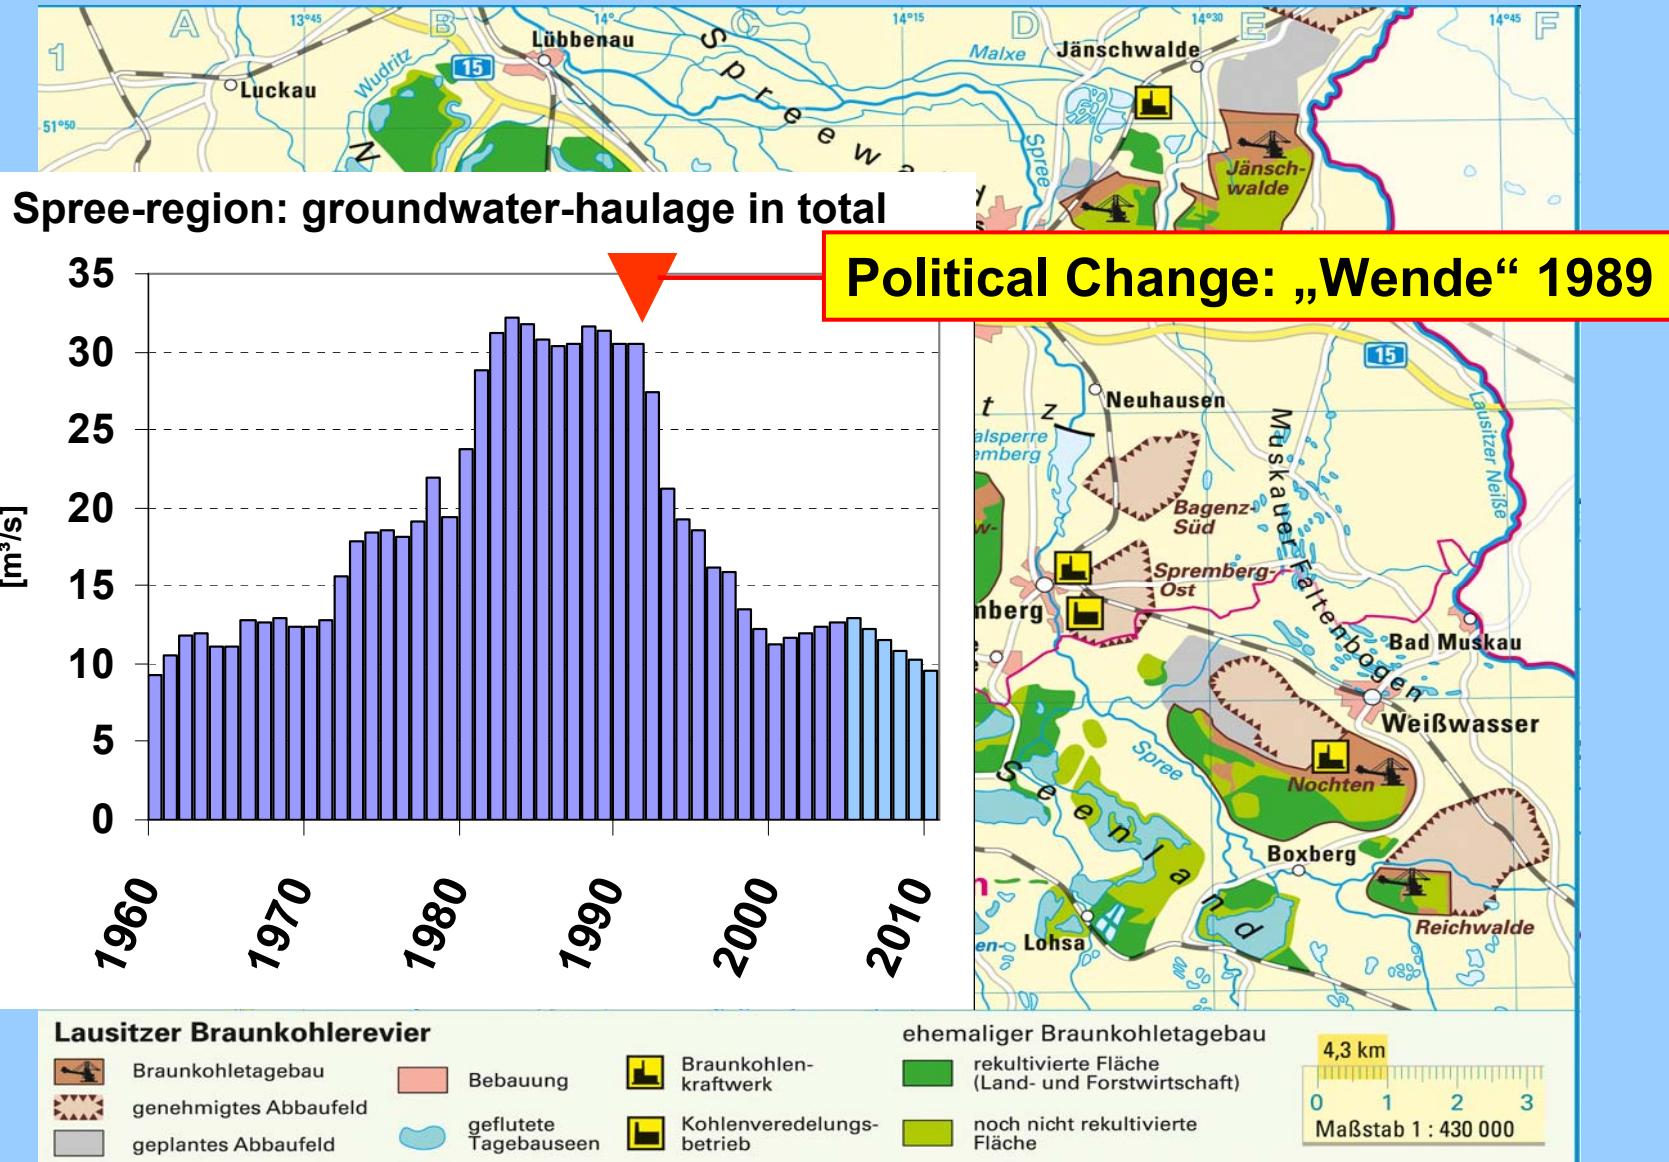

...Coincidence?

Large Areas of the Havel- and the Schwarze Elster-catchments are situated in the Lausitz region with it's widespread lignite open-cast mining

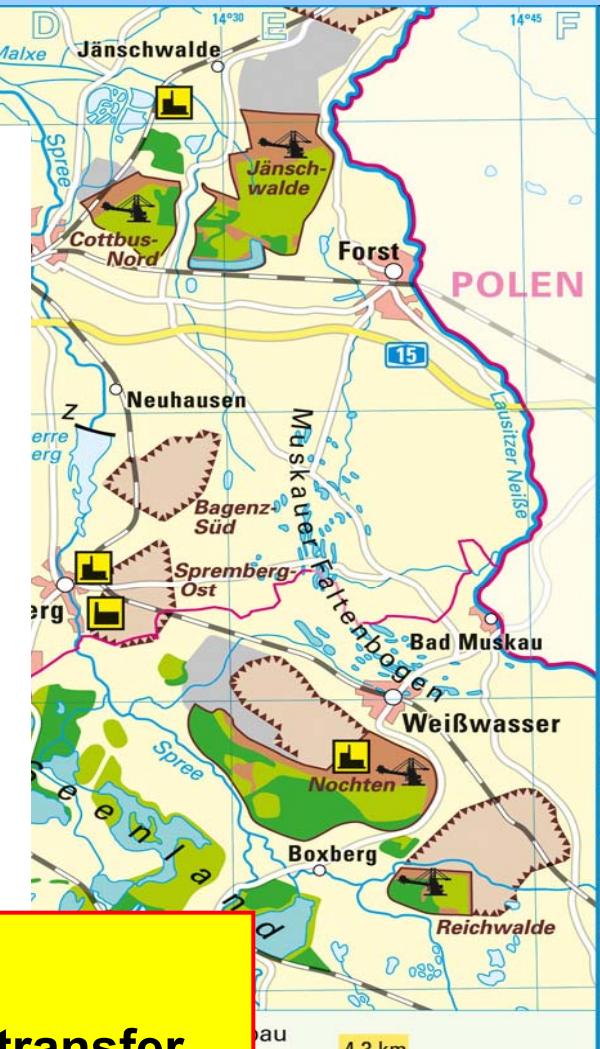

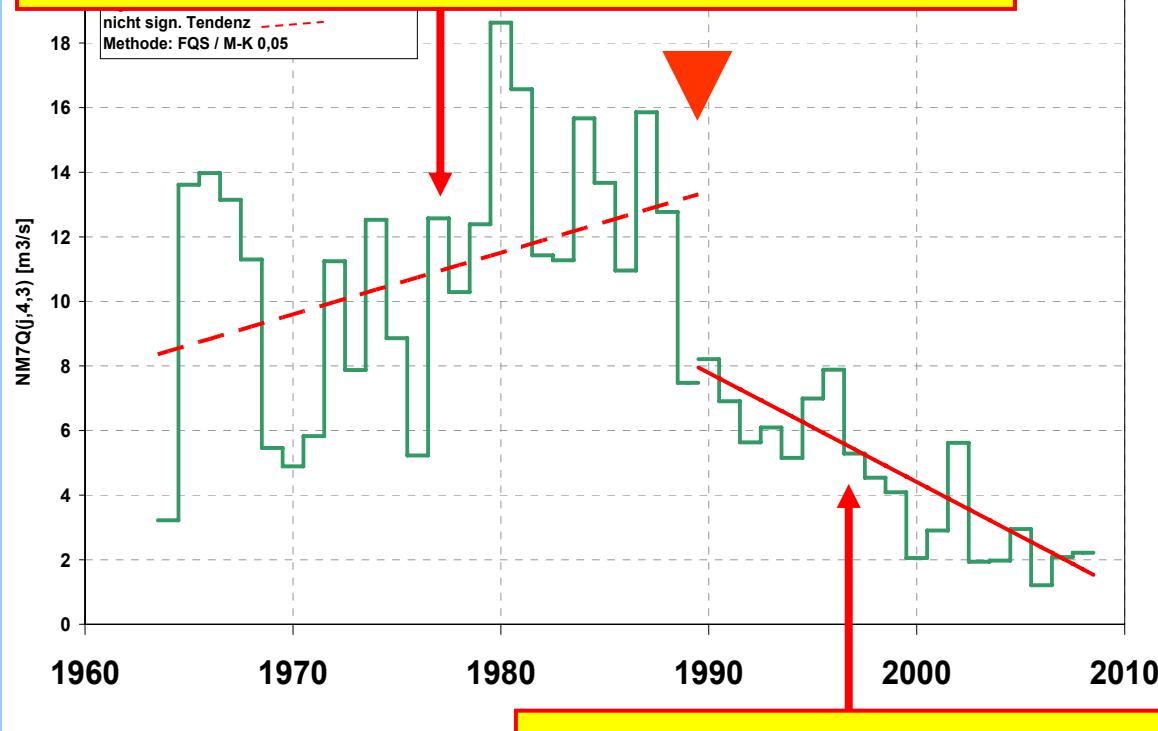

Socio-Economic Influence on Runoff: Lignite and Politics

Socio-Economic Influence on Runoff: Lignite and Politics

...before 1989: Groundwater-transfer into surface-waters (pumping-water from open-cast lignite-mining aquifers)

...after 1989:

- reducing of groundwater transfer,
- surface water-transfer into the open pits (recultivation)

After all (1): Trivial theses on modelling in general

Modelling close to reality requires understanding of the system.

Understanding of the system in hydrology arises from closest-possible knowledge of the existing structures in both past and present.

Thus, understanding of the system implies data-analysis, which means identification of the responsible factors and processes to avoid results of accidental nature (and not to rely on parametrics to optimize the model fitting).

After all, modelling without consideration of comprehensive data-analysis means to accept a higher probability of uncertainties and mistakes.

Data-analysis as the initial part of the modelling-work has to be as profound as possible. With it, pure statistical analysis without solid hydrological or (preferably: and) regional background-knowledge is not reliable.

After all (2): Trivial theses on socio-economics within hydrological modelling

Socio-economic influence subsums various anthropogenic effects on the water-cycle. Therefore, it is an important, but in the whole hardly quantifiable protagonist within the water-cycle. Socio-economic development (via it's dependant process-elements) is able to mark it's footprint on the discharge-regime even of larger watercourses.

The consideration of socio-economic items in context of hydrological modelling helps to improve the realism and practicability of the model-results

Therefore, it is recommendable to implement socio-economic effects into the hydrological modelling (which, of course, is to be understood as a close compound together with the initial data-analysis): for interpretation and evaluation purposes and to get insights about possible future developments.

Thank you for your kind
attention !
